The General Principles of Continuum Thermomechanics

In this chapter, we develop a general theory of continuum thermomechanics. We caution the reader that while our approach to the first law of thermodynamics is universally accepted, the same cannot be said for our approach (or anyone else's) to the second law of thermodynamics.
6.1. Introduction

It is only within the last few years that continuum thermodynamics has reached a stage of development that allows for a rational presentation comparable to our treatment of continuum mechanics. We will be introducing some new concepts such as heat flux, entropy, temperature, etc. These will be undefined primitives of the same rank as stress, mass, time, etc. Whenever you reach a mental block because you do not have a "feeling" for the thermodynamical notions and associated principles, ask yourself if you really understand force and balance of linear momentum. Our comfortable feeling about mechanics is due to familiarity and a knowledge of several centuries of successes with the theory.

Some comments on the modern literature are in order. The first three items on the supplementary reading list for this section are quite readable research papers which got the modern developments started. The 1964 paper by Coleman and Nigdel is probably the best, although the 1963 paper by Coleman and Noll is the most significant in that it was first. We have made no explicit reference to the many papers that followed these three. Most of them are rather difficult because of the mathematics involved. Probably the best place to start is with the recent text
Rational Thermodynamics by Truesdell. As with most of
Truesdell's expository works, this monograph is entertaining
as well as informative.

It should be emphasized that continuum thermomechanics
is in a rapid state of development. It can now be presented
rationally and it has enjoyed numerous successes, but it
may not be in its final form.

6.2. Conservation of Energy: The First Law

The first law of thermodynamics is a statement of energy balance which calls for the introduction of three new thermodynamical concepts. We choose to do this in terms of the spatial variables \( \mathbb{R}^3 \).

For the remainder of this section, we consider a body \( \mathcal{B} \) and a motion \( \{ \mathcal{E}(\cdot, t) \} \). As before, \( \mathcal{Q} \) denotes an arbitrary part of \( \mathcal{B} \); and \( \mathcal{Q}_t \) is the region of \( \mathcal{E} \) that \( \mathcal{Q} \) occupies at time \( t \). The trajectory of \( \mathcal{Q} \) under \( \{ \mathcal{E}(\cdot, t) \} \) is denoted by \( \mathcal{O}_t \).

We assume that

\[
\exists \text{ a scalar-valued function } \mathbb{E} \text{ on } \mathcal{O} \ni \int_{\mathcal{Q}_t} \mathbb{E}(x, t) \rho(x, t) \, dx = \mathbb{E}(\mathcal{Q}_t)
\]

represents the internal energy of part \( \mathcal{Q} \) at time \( t \). The function \( \mathbb{E} \) is smooth in \( x \) and \( t \). The scalar \( \mathbb{E}(x, t) \) is called the specific internal energy (per unit mass) at the point \( x \) at time \( t \).

1. Definition 2.4.5.
2. Definition 2.6.7.
3. Definition 2.4.3.
In order to handle the flow of heat across surfaces in the body, we assume

For each unit vector $\mathbf{n}$, there exists a scalar-valued function $q_{n}$ on $\mathbf{n}$ such that

$$
\mathcal{F}_{n}(x, t) dx,
$$

where $\mathbf{n}(x, t)$ is the unit outward normal to $\partial \Omega$ at $x$, represents the rate of energy flow into part $\Omega$ at time $t$ due to heat conduction across $\partial \Omega$. For each $\mathbf{n}$ and $t$, the field $q_{n}(\cdot, t)$ is smooth. The scalar $q_{n}(x, t)$ is called the heat flux at the point $x$ on the surface through $x$ with unit normal $\mathbf{n}$ at $x$ at time $t$.

It is of course appropriate to think of $q_{n}$ as the "surface heat supply per unit area per unit time".

It should be clear that the heat flux $q_{n}$ is similar in concept to the stress vector $\mathbf{t}_{n}$, as in continuum mechanics, measure theory is the most appropriate vehicle for dealing with these concepts. Following Noll's approach to the stress vector, Doan and Williams have shown that the heat flux

1 Cf. (E) on p. 2.112.
flux can depend on no characteristic of the surface other than its normal.

Analogous to the body force, we assume that there exists a scalar-valued function \( r \) on \( \mathcal{O} \),

\[
\int_{\partial \mathcal{O}} r(\mathbf{x}, t) \rho(\mathbf{x}, t) \, d\mathbf{x}
\]

represents the rate of heat flow into part \( \mathcal{O} \) at time \( t \) due to other bodies (than \( \mathcal{O} \)). For each \( t \), the field \( r(\mathbf{x}, t) \) is continuous. The scalar \( r(\mathbf{x}, t) \) is called the \textit{extrinsic heat supply} (per unit mass and per unit time) at the point \( \mathbf{x} \) at time \( t \).

Combining \((E_2)\) and \((E_3)\), we have

**Definition 6.2.1.** The rate of energy flow into part \( \mathcal{O} \) at time \( t \) due to thermal effects is

\[
\bar{Q}(\mathcal{O}) = \int_{\partial \mathcal{O}} \mathbf{q}(\mathbf{x}, t) \, d\mathbf{x} + \int_{\mathcal{O}} r(\mathbf{x}, t) \rho(\mathbf{x}, t) \, d\mathbf{x}
\]

We also need two familiar\(^2\) mechanical terms.

\(^1\)Often heat radiation.

\(^2\)See §2.11.
Definition 6.2.2. The kinetic energy of part \( P \) at time \( t \) is
\[
K(\mathcal{Q}_t) = \frac{1}{2} \int_{\mathcal{Q}_t} \left| \mathbf{v}(x,t) \right|^2 \rho(x,t) \, dx.
\]
The power of the forces on part \( P \) at time \( t \) is
\[
P(\mathcal{Q}_t) = \int_{\mathcal{Q}_t} \mathbf{f}(x,t) \cdot \mathbf{v}(x,t) \, dx + \int_{\partial \mathcal{Q}_t} \mathbf{b}(x,t) \cdot \mathbf{n}(x,t) \rho(x,t) \, dA.
\]

These quantities are related through the following axiom:

Principle of Conservation of Energy \(^2\)

\[
(T_i) \quad \frac{d}{dt} \left[ K(\mathcal{Q}_t) + E(\mathcal{Q}_t) \right] = P(\mathcal{Q}_t) + Q(\mathcal{Q}_t)
\]

\( \forall \mathcal{Q} \subset \mathcal{B} \) and \( \forall \) motions \( \{ K(\cdot,t) \} \).

We note that an "equivalence" of heat and work is implicit in this axiom. We assume from now on that energy is balanced.

Let \( K \) and \( P \) act now before local arguments.

In order to establish the local form of \((T_i)\), we observe the analogy between the heat flux \( q \) and

\[^1\text{Often rate of work.}\]
\[^2\text{Often principle of energy balance or first law of thermodynamics.}\]
the stress vector $\tau_n$. Thus we follow the developments in § 2.11 that lead from a global statement of balance of linear momentum to a local statement of momentum balance.

Applying balance of energy to a pill-box-shaped part leads to: Need polygonal pillows if don't assume continuity.

**Theorem 6.2.1.** For each unit vector $\vec{n}$ and $\vec{v}(x,t) \in \mathcal{V}$

$$\tau_{\hat{n}}(x,t) = -\tau_{\hat{n}}(x,t).$$

**Proof.** Exercise 6.2.1. □

Next let $\{\vec{e}_i\}$ be an orthonormal basis for $\mathcal{V}$ and introduce the scalars

$$\tau_{\vec{e}_i}(x,t) = \tau_{\vec{e}_i}(x,t).$$

Using this notation and applying (T$_i$) to a part shaped as a tetrahedron with sides normal to the base vectors and slant face normal to $\vec{n}$ yields (with the aid of Theorem 6.2.1)

**Theorem 6.2.2.** For a vector-valued function $\tau$ on $\mathcal{V}$

exists for each unit vector $\vec{n}$

$$\tau_{\hat{n}}(x,t) = \tau(x,t) \cdot \vec{n} \quad \forall (x,t) \in \mathcal{V}.$$
Moreover, for each \( t \), the field \( \mathbf{q}(\cdot, t) \) is smooth on \( \Omega_t \). \( \mathbf{q}(x, t) \) is called the heat flux vector at the place \( x \) at time \( t \).

Proof. Exercise 6.2.2. \( \Box \)

In terms of the heat flux vector, we can express the total heat flow as

\[
Q(\Omega_t) = \int_{\Omega_t} \mathbf{q}(x, t) \cdot n(x, t) \, dx + \int_{\partial \Omega_t} r(x, t) \mathbf{p}(x, t) \, dS;
\]

or, using the divergence theorem,\(^2\)

\[
Q(\Omega_t) = \int_{\Omega_t} \nabla \cdot \mathbf{q}(x, t) + r(x, t) \mathbf{p}(x, t) \, dx
\]

As an immediate consequence of the reduced transport theorem\(^3\), we have

\[
\frac{d}{dt} E(\Omega_t) = \frac{d}{dt} \int_{\Omega_t} E(x, t) \mathbf{p}(x, t) \, dx = \int_{\Omega_t} E(x, t) \mathbf{p}(x, t) \, dx.
\]

1 The notation \( \mathbf{q} = -\mathbf{k} \) or \( \mathbf{q} = -\mathbf{k} \) is also quite common.

2 Theorem 1.23.1.

3 Exercise 2.10.5.
where the superscript dot, \( (\cdot) \), denotes the material time derivative:

\[
\dot{\varepsilon}(x, t) = \frac{\partial \varepsilon}{\partial t}(x, t) + \nabla \times \dot{\mathbf{v}}(x, t) - \nabla \times \mathbf{E}(x, t). \tag{1}
\]

Finally, in the present notation, the energy transfer theorem\(^2\) asserts that

\[
\frac{d}{dt} K(Q_t) = P(Q_t) - \int_{Q_t} \left[ \dot{\varepsilon}(x, t) \dot{\mathbf{v}}(x, t) \right] dx,
\]

where \( \mathbf{J} \) is the stress tensor and \( \mathbf{D} \) is the symmetric part of the spatial velocity gradient.

Putting the above results into (T) yields

\[
\int_{Q_t} \left\{ \dot{\varepsilon}(x, t) p(x, t) - \nabla \times \left[ \dot{\mathbf{v}}(x, t) \right] - \nabla \times \mathbf{E}(x, t) - \mathbf{J}(x, t) p(x, t) \right\} dx = 0.
\]

Since this must hold \( \forall Q \subset B \) and since all of the steps are reversible, we have proven

**Theorem 6.2.3.** (Local Energy Balance) Energy is conserved \(^3\) if

---

1. Recall our locale notational agreement (p. 2.4.6).
2. Theorem 2.11.5.
3. I.e., (T) holds.
\[ \nabla \cdot \hat{\varphi}(x,t) + \rho(x,t) \dot{\varphi}(x,t) + \tau \left[ \frac{\partial}{\partial x_j} \hat{\varphi}(x,t) \right] = \rho(x,t) \ddot{\varphi}(x,t) \]

\[ \forall (x,t) \in \Omega. \]

In Theorem 6.2.3, the superscript caret, \(^\hat{\cdot}\), emphasizes the use of the spatial variables.

Supplementary Reading

Same as for §6.1

---

Recall our first notational agreement (p.245).
6.3. The Dissipation Inequality. The Second Law

First we need the concept of temperature. Temperature measures how "hot" a body is, just as the notion of point tells us "where" a body is. Experience indicates that bodies cannot get too "cold," i.e., the temperature is bounded below. Taking this bound to be zero gives us an absolute temperature scale.

We assume that

$$\exists \, \text{a strictly positive scalar-valued function } \theta \text{ on }$$

$$\mathbb{R} \ni \theta(x, t) > 0 \text{ is the absolute temperature at the place } x \text{ at the time } t. \text{ The function } \theta$$

$$\text{is smooth in } x \text{ and } t \text{ together.}$$

The second law of thermodynamics is usually put forth as representing a certain irreversibility in natural processes. For example, it is observed that while mechanical work can always be totally dissipated as heat energy, heat cannot always be totally converted into mechanical work; also while a body generally becomes hotter if we put energy (work and/or heat) into it, a corresponding cooling does not necessarily release this same

---

amount of energy.

In order to proceed, we follow Tienstall's account of C. Eckart's motivation for the notion of entropy and the second law. We momentarily revert to homogeneous processes where all of the relevant fields are uniform over the body. The observation that there is a limit to the rate at which heat can be put into a body can be stated mathematically as

\[ Q \leq B. \]

Since \( \Theta > 0 \), we can define a new quantity \( H \) (the entropy) by

\[ H = \int_{t_0}^{t} \frac{B}{\Theta} \, dt. \]

Then

\[ \dot{H} = \frac{B}{\Theta}, \]

and \( Q \leq B \) is equivalent to

\[ \dot{H} \geq \frac{Q}{\Theta}. \]

This is the Clausius-Planck inequality; it is generally accepted as the appropriate statement of the second law of thermodynamics for homogeneous processes.

---

1. "Rational Thermodynamics", p. 11.
The "derivation" above is subject to the criterion that there are many upper bounds like $B$ throughout continuum physics, but they seldom make an explicit appearance in the theory — only in the practice of the theory. For example, velocities in Newtonian mechanics are bounded by the speed of light; but the speed of light never appears in classical mechanics. On the other hand, the second law of thermodynamics attempts to model a physical notion vastly different from the usual balance principles with which we are more familiar.

With the Clausius-Planck inequality in mind, we assume that

$$\exists \text{ a scalar-valued function } \gamma \text{ on } \mathcal{I} \ni$$

$$\int_{\mathcal{Q}_t} \gamma(x, t) \rho(x, t) \, dx = H(\mathcal{Q}_t)$$

represents the entropy of part $\mathcal{P}$ at time $t$. The function $\gamma$ is smooth in $x$ and $t$ together. The scalar $\gamma(x, t)$ is called the specific entropy (per unit mass) at the point $x$ at time $t$.

We generalize the Clausius-Planck inequality to general thermo-mechanical processes with the following axiom.
The Dissipation Inequality

\[ \frac{d}{dt} H(\Omega_t) = \int_{\Omega_t} \frac{1}{\eta(\xi, t)} \frac{\partial \mathbf{v}(\xi, t)}{\partial \xi} \cdot \mathbf{v}(\xi, t) \, d\xi + \int_{\Omega_t} \frac{1}{\eta(\xi, t)} \rho(\xi, t) \, d\xi \]

\[ \forall \Omega \subseteq \mathbb{R}^3 \text{ and all motions } \{ \mathbf{v}(\cdot, t) \}. \]

We note that putting the temperature under the integral signs in passing from the Clausius–Planck inequality to the dissipation inequality is similar to putting the lever arm under the integral sign in passing from the angular momen theorem of particle mechanics to the angular momen postulate of continuum mechanics.

Even though the dissipation inequality has led to numerous major successes and advances in continuum thermomechanics, it has not (yet?) met universal acceptance as the appropriate form of the second law of thermodynamics.

Exercise 6.3.1. An alternative (but not equivalent) generalization of the Clausius–Planck inequality is

After the entropy inequality, the second law of thermodynamics, the Clausius-Duhem inequality, or the Clausius-Duhem-Neuhold-Toupin inequality.
\[ p \dot{\mathbf{v}} = \nabla \cdot \mathbf{f} + \rho \frac{\mathbf{f}}{\mathbf{e}} \cdot \nabla \mathbf{e} \]

In what sense is this a generalization of \( \dot{\mathbf{H}} = \frac{\mathbf{Q}}{\mathbf{e}} \)?

**Theorem 6.3.1.** (Local Dissipation Inequality) The dissipation inequality \( \dot{\mathbf{H}} \) is satisfied if

\[ p(x,t) \dot{\mathbf{H}}(x,t) = \nabla \cdot \left( \frac{\mathbf{f}(x,t)}{\mathbf{e}(x,t)} \right) + p(x,t) \frac{\mathbf{f}(x,t)}{\mathbf{e}(x,t)} \cdot \nabla \mathbf{e}(x,t) \]

where \( \dot{\mathbf{H}}(x,t) = \frac{\partial \mathbf{H}(x,t)}{\partial t} + \mathbf{e}(x,t) \cdot \nabla \mathbf{H}(x,t) \) is the material time derivative.

**Proof.** Exercise 6.3.2. \( \square \)

It is sometimes convenient to combine the local dissipation inequality with local energy balance to obtain

**Theorem 6.3.2.** Granting local energy balance, the local dissipation inequality is equivalent to

\[ p(\dot{\mathbf{v}} - \dot{\mathbf{e}}) + \nabla (\mathbf{T} \mathbf{D}) + \frac{1}{2} \mathbf{q} \cdot \nabla \mathbf{e} \geq 0 \]

**Proof.** Exercise 6.3.3. \( \square \)

**Theorem 6.2.3.**

As usual, the superscript dot denotes material time derivatives.
It is often mathematically convenient to replace the specific internal energy $\varepsilon$ by the specific free energy $\psi$ as defined below, when using $\Theta$ as independent thermodynamical variable.

**Definition 6.3.1.** The specific free energy is

$$\psi = \varepsilon - \Theta \eta.$$

Since $\psi = \varepsilon - \eta \Theta - \Theta \Theta$, it follows from Theorems 6.2.3 and 6.3.2 that local energy balance and local dissipation can be expressed in terms of the free energy as given below.

**Theorem 6.3.3.** The local energy is balanced iff

$$\nabla \cdot \dot{\Psi} + \rho r + t_e (T, \dot{\Theta}) = \rho (\dot{\psi} + \eta \dot{\Theta} + \Theta \dot{\eta}).$$

Mainting local energy balance, the local dissipation inequality is equivalent to

$$-\rho (\dot{\psi} + \eta \dot{\Theta}) + t_e (T, \dot{\Theta}) + \Theta \Theta \cdot \nabla \Theta \geq 0.$$

The inequalities of Theorems 6.3.2 and 6.3.3 are sometimes called reduced local dissipation inequalities. They are "reduced" by taking into account local energy balance.

The major contribution of Coleman and Noll in continuum thermomechanics was their utilization of the local dissipation

*Show this using the spatial description as Exercise 6.3.4.*
inequality as a restriction on constitutive equations, in preparation for this in subsequent chapters, we make the following definition.

Definition 6.3.2. Given a body \( \mathcal{B} \), the set of eight functions

1) \( \mathbf{X} \) --- the motion,
2) \( \mathbf{T} \) --- the stress tensor,
3) \( \mathbf{F} \) --- the body force,
4) \( E \) --- the specific internal energy (or \( \mathcal{U} \) --- the specific free energy),
5) \( q \) --- the heat flux vector,
6) \( r \) --- the extrinsic heat supply,
7) \( \Theta \) --- the absolute temperature,
8) \( \eta \) --- the specific entropy.

is said to constitute a thermomechanical process if all of our smoothness hypotheses are satisfied and if the linear momentum is balanced, the angular momentum is balanced, and the energy is balanced.

Exercise 6.3.5. Roughly speaking, the term adiabatic in thermodynamics refers to "no heat flow". In order to be precise, we consider three variations and describe them.

"It is understood that the mass density \( \rho \) is part of the prescription of the body \( \mathcal{B} \) and that mass is conserved."
in rather nonuniversal terminology:

\[ q = 0, r = 0 \quad \text{--- completely adiabatic}; \]
\[ Q(\mathbf{v}_t) = 0 \quad \text{--- globally adiabatic}; \]
\[ \rho \cdot \nabla \cdot \mathbf{q} + \rho r = 0 \quad \text{--- locally adiabatic}. \]

Show that a completely adiabatic thermomechanical process is compatible with the second law of thermodynamics iff \( \mathcal{W} [ \mathcal{W}(x, t) = \mathcal{W}(x(t), \theta)] \) is a monotone non-decreasing function of \( t \) for each particle \( x \in \mathbb{B} \), i.e., the entropy does not decrease in a completely adiabatic process.

Supplementary Reading

Same as for \( \S 6.1 \)

\[ \text{I.e., } (T_2) \text{ is satisfied}. \]
Chapter 7

Thermoelasticity

The full implications of the second law of thermodynamics cannot be realized without consideration of the constitutive equations for the body under study. The thermomechanics of simple materials that have a memory of the past is mathematically very difficult. In this chapter, we see how the second law works by considering the much easier case of elastic bodies.
7.1. Constitutive Assumptions. Equipresence

Now that we are taking thermal effects into account, we are faced with having to write constitutive equations not only for the stress but also for the heat flux, the entropy, etc. To help us do this, we employ Timoshenko's Principle of Equipresence:

An independent variable present in one constitutive equation of a body should be present in all unless its presence is ruled out by material symmetry, material indifference, or the basic laws.

Actually, "principle" is too strong a name to attach to the notion of equipresence. It is really intended as a guide for theorists in constructing constitutive equations. It is just a formal way of saying that if you do not have a good reason for leaving a variable out of a constitutive equation, it is safer to leave it in.

In accordance with equipresence, we make the following constitutive assumptions for thermoelasticity.

Definition 7.1.1. A body $B$ is said to be thermoelastic with respect to the reference configuration if for each particle $x \in B$ there are response functions $T^n, \theta^n, \nabla^n$. 
\[ \bar{g}^x_{\nu} \Rightarrow \]
\[ I = \bar{T}^x_{\nu} (E_n(x,t), \Theta(x,t), \varphi(x,t)) \]
\[ \Psi = \bar{T}^x_{\nu} (E_n(x,t), \Theta(x,t), \varphi(x,t)) \]
\[ \eta = \bar{T}^x_{\nu} (E_n(x,t), \Theta(x,t), \varphi(x,t)) \]
\[ \bar{g} = \bar{T}^x_{\nu} (E_n(x,t), \Theta(x,t), \varphi(x,t)) \]

Here
\[ \varphi(x,t) = \nabla \Theta(x,t) \]

is the spatial temperature gradient, and, as usual, \( x, \bar{x}, \) and \( \bar{x} \) are related through
\[ \bar{x} = \bar{x}(x) \]
\[ \bar{x} = \bar{x}(x,t) \]

with \( \bar{x} \) being the motion. The response functions are assumed to be smooth on their common domain \( \Omega \), and the values of \( I \) are symmetric.

It is natural to think of the stress in elasticity as dependent on the deformation gradient, and this puts \( E_n \) into all of the constitutive equations. Similarly, the temperature gradient is automatically thought of as the main driving mechanism for the heat flux. The temperature itself could seem to be an appropriate variable in all of the constitutive equations.\(^1\)

We will make no use of the symmetry of \( I \), and we will find out
The right hand sides of the constitutive equations are somewhat scrambled up between the spatial and referential descriptions. This was the reason for not indicating any preference in the left hand side. The following notation fits in with schemes introduced previously:

\[
\hat{\sigma}(x,t) = \hat{\sigma}(x(x,t), t), \\
\hat{\tau}(x,t) = \hat{\tau}(x(x,t), t), \\
\hat{\omega}(x,t) = \hat{\omega}(x^{-1}(x), t), \\
\hat{\theta}(x,t) = \hat{\theta}(x^{-1}(x), t),
\]

Exercise 7.1.1. Show that

\[
\nabla_{\omega}(x,t) = F^T(x,t) \hat{\theta}(x,t).
\]

We are considering the class of materials that is elastic in the sense that the dependent variables in the constitutive equations depend on the present values of the independent variables. Since we are attempting to take into account thermal effects, the resulting theory is called thermoelasticity.

See Definitions 2.46 and 2.6.2.
It should be clear that because of the body force and intrinsic heat supply, the laws of balance of linear momentum, angular momentum, and energy will place no restrictions on the forms of the response functions except that the values of $\mathbf{T}$ must be symmetric tensors. In the next section, we will see that the dissipation inequality also places restrictions on the response functions.

Supplementary Reading

Same as for §6.1 + Wang and Turcotte
7.2. Consequences of the Dissipation Inequality

We recall from Theorem 6.3.3 that the reduced dissipation inequality can be written in the local form

$$-\rho \left( \dot{\psi} + \eta \theta \right) + t \varepsilon (T^T) + \frac{1}{2} \mathbf{q} \cdot \nabla \theta \geq 0,$$

where \( \psi \) and \( \theta \) denote material time derivatives, e.g.

$$\dot{\psi} (x, t) = \frac{\partial \psi}{\partial t} (x, t) + \mathbf{v} (x, t) \cdot \nabla \psi (x, t).$$

Here we have purposely ignored the symmetry of the stress tensor and have written the stress power as \( t \varepsilon (T^T) \) as it first appeared in the energy transfer theorem.\(^2\)

It will be more convenient here to work with the so-called variables, and thus in the usual manner we introduce

$$\psi_0 (x, t) = \hat{\psi} (\mathbf{x}_0 (x, t), t) = \tilde{\psi} (\mathbf{x}^{-1} (x), t),$$

Exercise 7.2.1. Using the above notation, show that

$$\dot{\psi} = \frac{\partial \psi_0}{\partial t} (x, t) = \frac{\partial \tilde{\psi}}{\partial t} (x, t).$$

\(^1\)Theorem 2.11.4,

\(^2\)Theorem 2.11.5,

\(^3\)See Definitions 2.4.6 and 2.6.2,
Our next step is to substitute the constitutive equations of the previous section into the dissipation inequality. To make this substitution as easy as possible, we introduce a fixed orthonormal basis \( \{ \mathbf{e}_i \} \) for \( \mathbb{H}_3 \) and work in terms of components. Thus

\[
\psi = \psi_n(x, t) = \bar{\Phi}_n^x \left( F_n^x(x, t), \Theta^x, \mathbf{g}^x \right)
\]

\[
= \bar{\Phi}_n^x \left( F_n^x \mathbf{v}^x(x, t), \Theta^x, \mathbf{g}^x \right)
\]

\[
\psi = \frac{\partial \bar{\Phi}_n^x}{\partial F_n^x} \frac{\partial F_n^x}{\partial t} + \frac{\partial \bar{\Phi}_n^x}{\partial \Theta^x} \frac{\partial \Theta^x}{\partial t} + \frac{\partial \bar{\Phi}_n^x}{\partial \mathbf{g}^x} \frac{\partial \mathbf{g}^x}{\partial t}
\]

From Theorem 2.6.3,

\[
\frac{\partial F_n^x}{\partial t} = \mathbf{b}_n \cdot F_n^x
\]

\[
\frac{\partial \Theta^x}{\partial t} = \mathbf{b}_n \cdot \mathbf{g}^x
\]

where we are employing the summation convention on all repeated indices. Then,

\[
\frac{\partial \bar{\Phi}_n^x}{\partial F_n^x} \frac{\partial F_n^x}{\partial \mathbf{v}^x} \frac{\partial \mathbf{v}^x}{\partial t} = \frac{\partial \bar{\Phi}_n^x}{\partial F_n^x} \left( \mathbf{b}_n \cdot F_n^x \right)
\]

"This imprecision should cause no confusion."
We define the tensor $\frac{\partial \bar{\Psi}_n^x}{\partial F_n}$ through

$$\frac{\partial \bar{\Psi}_n^x}{\partial F_n} = \frac{\partial \bar{\Psi}_n^x}{\partial F_n} \langle \psi \rangle \otimes \langle \psi \rangle$$

Or

$$\left( \frac{\partial \bar{\Psi}_n^x}{\partial F_n} \right) \langle ij \rangle = \frac{\partial \bar{\Psi}_n^x}{\partial F_n} \langle ij \rangle$$

Then

$$\frac{\partial \bar{\Psi}_n^x}{\partial F_n} \frac{\partial F_n}{\partial t} = \left[ \frac{\partial \bar{\Psi}_n^x}{\partial F_n} \right] \langle ij \rangle L_n$$

$$\bar{\Psi}_n \left[ \frac{\partial \bar{\Psi}_n^x}{\partial F_n} \right] L_n^T = \left[ \frac{\partial \bar{\Psi}_n^x}{\partial F_n} \right] L_n^T$$

Similarly, we define the vector $\frac{\partial \bar{\Psi}_n^x}{\partial g_n}$ through

$$\frac{\partial \bar{\Psi}_n^x}{\partial g_n} = \frac{\partial \bar{\Psi}_n^x}{\partial g_n} \langle i \rangle$$
\[
\frac{\partial \Psi_n^x}{\partial g_n} \langle i \rangle = \frac{\partial \Psi_n^x}{\partial g_n} \langle i \rangle
\]

Then
\[
\frac{\partial \Psi_n^x}{\partial g_n} \frac{\partial \langle i \rangle}{\partial t} = \frac{\partial \Psi_n^x}{\partial g_n} \cdot \frac{\partial g_n}{\partial t}
\]

Thus, we can write
\[
\dot{\Psi} = \tau \left[ T_n^T \left( \frac{\partial \Psi_n^x}{\partial F_n} \right) F_n \right] + \frac{\partial \Psi_n^x}{\partial F_n} \frac{\partial \Theta_n}{\partial t} + \frac{\partial \Psi_n^x}{\partial g_n} \cdot \frac{\partial g_n}{\partial t}
\]

and hence we have

**Theorem 7.2.1.** For a thermoelastic body, the reduced local dissipation inequality can be written as

\[
\tau \left[ T_n^T - \rho \left( \frac{\partial \Psi_n^x}{\partial F_n} \right) F_n \right] \dot{\Theta}_n - \rho \left( \frac{\partial \Psi_n^x}{\partial \Theta_n} + \frac{\partial \Psi_n^x}{\partial g_n} \right) \dot{\Theta}_n \\
- \rho \frac{\partial \Psi_n^x}{\partial g_n} \cdot \frac{\partial g_n}{\partial t} + \frac{1}{\Theta_n} \frac{\partial \Psi_n^x}{\partial g_n} \cdot g_n \geq 0.
\]

Following Coleman and Noll (1963), we will view this inequality as placing restrictions on the response functions rather than on thermomechanical processes. In other words, we will restrict the response functions in such a way that the dissipation inequality is satisfied for all thermomechanical processes corresponding to the constitutive equations.
Definition 7.2.1. A thermomechanical process is admissible if it is consistent with the constitutive equations under consideration; it is local if the domain of the process is restricted so as to involve a part of the body and a finite time interval.

Thus, in the present context, an admissible thermomechanical process must satisfy the constitutive equations of Definition 7.1.1.

The actual dissipation inequality from Theorem 7.2.1 while accounts for the constitutive then leads us to

Theorem 7.2.2. A necessary and sufficient condition that every admissible local process corresponding to the thermoelectric constitutive equations

\[ J = \mathcal{T}_x^\infty (\mathbf{F}, \theta, g) \]
\[ V = \mathcal{V}_x^\infty (\mathbf{F}, \theta, g) \]
\[ \eta = \mathcal{\eta}_x^\infty (\mathbf{F}, \theta, g) \]
\[ q = \mathcal{q}_x^\infty (\mathbf{F}, \theta, g) \]

\[ \text{Definition 6.3.2.} \]

\[ \text{2 ie, the functions of the process are related through the constitutive equations.} \]

\[ \text{3 Definition 2.5.7.} \]
satisfy the reduced local dissipation inequality if and only if each of the following four statements hold:

(i) The response functions \( \overline{T}^x, \overline{\Psi}^x, \) and \( \overline{\eta}^x \) are independent of the spatial temperature gradient \( \varphi \), i.e.,
\[
\overline{T}^x(\bar{E}_n, \varphi), \quad \overline{\Psi}^x(\bar{E}_n, \varphi), \quad \overline{\eta}^x(\bar{E}_n, \varphi).
\]

(ii) The response function \( \overline{T}^x \) is determined from the response function \( \overline{\Psi}^x \) by the stress relation
\[
\overline{T}^x(\bar{E}_n, \varphi) = \rho \bar{E}_n \left[ \frac{\partial \overline{\Psi}^x}{\partial \bar{E}_n} (\bar{E}_n, \varphi) \right].
\]

(iii) The response function \( \overline{\eta}^x \) is determined from the response function \( \overline{\Psi}^x \) by the entropy relation
\[
\overline{\eta}^x(\bar{E}_n, \varphi) = -\frac{\partial \overline{\Psi}^x}{\partial \varphi} (\bar{E}_n, \varphi).
\]

(iv) The response function \( \overline{T}^x \) obeys the heat conduction inequality
\[
\overline{T}^x(\bar{E}_n, \varphi, \varphi) \geq 0.
\]

Proof. The sufficiency of these four conditions follows immediately from the form of the reduced local dissipation inequality given in Theorem 7.2.1. In order to demonstrate
Here necessity, we need the following.

**Lemma** Given \( x^* \in \mathcal{X}(\mathcal{B}) \), real \( t^* \), \( F^* \in \mathcal{F}(\mathcal{V}) \) with det \( F^* \neq 0 \), \( \Theta^* > 0 \), \( g^* \in \mathcal{V} \), and also given \( A \in \mathcal{M}(\mathcal{V}) \), \( x^* \in \mathcal{X} \); \( E \) an admissible local thermomechanical process with

\[ E(x^*, t^*) = F^* \quad \text{and} \quad \frac{\partial E(x^*, t^*)}{\partial t} = A, \]

\[ \Theta(x^*, t^*) = \Theta^* \quad \text{and} \quad \frac{\partial \Theta(x^*, t^*)}{\partial t} = \alpha, \]

\[ g(x^*, t^*) = g^* \quad \text{and} \quad \frac{\partial g(x^*, t^*)}{\partial t} = a. \]

**Proof of the Lemma**: Define \( x_n \) and \( \Theta_n \) by

\[ x_n(x, t) = \left[ F^* + (t-t^*)A \right] (x-x^*), \]

and

\[ \Theta_n(x, t) = \Theta^* + \alpha (t-t^*) + \left\{ F^{*T} \left[ g^* + (t-t^*)a \right] \right\} (x-x^*). \]

Clearly, this definition leads to the desired values at \((x^*, t^*)\). Also, det \( F_n(x, t) \neq 0 \) and \( \Theta_n(x, t) > 0 \) at least in some neighborhood of \((x^*, t^*)\).

We use this choice of \( x_n \) and \( \Theta_n \) to generate an admissible thermomechanical process by getting \( t, \mu, \nu, \)

\[ \text{This is the reason for considering local processes.} \]

\[ \text{Exercise 7.2.2.} \]
and $\eta$ from the constitutive equations; and then we choose $\beta$ and $\xi$ so as to balance momentum and energy. □

We now return to the proof of Theorem 7.2.2. Applying the reduced local dissipation inequality of Theorem 7.2.1 to the process constructed in the lemma yields

\[
\frac{\partial \bar{\psi}^{x^*}}{\partial E^*_x} (E^*, \theta^*, g^*) - \rho^* \tilde{\eta}^* \left[ \frac{\partial \bar{\psi}^{x^*}}{\partial E^*_x} (E^*, \theta^*, g^*) \right] L^*_x \]

\[
- \rho^* \left[ \eta_x^* (E^*, \theta^*, g^*) + \frac{\partial \bar{\psi}^{x^*}}{\partial \theta^*} (E^*, \theta^*, g^*) \right] a
\]

\[
- \rho^* \frac{\partial \bar{\psi}^{x^*}}{\partial g^*_0} (E^*, \theta^*, g^*) \cdot a + \frac{L^*_x (E^*, \theta^*, g^*)}{\theta^*} \frac{1}{\theta^*} \geq 0,
\]

where $x^* = x^{-1} (x^*)$, $\rho^* = \frac{P_x (x^*)}{\text{det} E^*_x}$, and $L^*_x = A (E^*)^{-2}$.

The desired results follow because of the arbitrariness of $x^*$, $E^*$, $\theta^*$, $g^*$, $L^*_x$, $x$, and $a$.

First we note that the dissipation inequality can be written as

\[
- \rho^* \frac{\partial \bar{\psi}^{x^*}}{\partial g^*_0} (E^*, \theta^*, g^*) \cdot a + f_1 (x^*, E^*, \theta^*, g^*, L^*_x, x) \geq 0.
\]

\footnote{Theorem 2.10.4,}
\footnote{Theorem 2.6.3,}
This can hold \( \forall x \) iff \( \frac{\partial \psi^x}{\partial g'} (E^*, \theta^*, g^*) = 0 \). Since \( x^*, E^*, \theta^* \), and \( g^* \) are arbitrary, we can write
\[
\frac{\partial \psi^x}{\partial g'} (E_n, \theta, g) = 0 \quad \text{or} \quad \psi = \psi^x (E_n, \theta).
\]

Exercise 7.2.3. Let \( a, b \in V_n \) and let \( a \) be real. Then prove that
\[
b \cdot a + a \geq 0 \quad \forall a \quad \Rightarrow b = 0.
\]

Next write the remaining portion of the dissipation inequality in the form
\[
-\mu^* \left[ \bar{\gamma}^x (E^*, \theta^*, g^*) + \frac{\partial \psi^x}{\partial g'} (E^*, \theta) \right] + f (x^*, E^*, \theta^*, g^*, \xi^*) \geq 0.
\]
This can hold \( \forall x \) iff \( \bar{\gamma}^x (E^*, \theta^*, g^*) + \frac{\partial \psi^x}{\partial g'} (E^*, \theta^*) = 0 \). Since \( x^*, E^*, \theta^* \), and \( g^* \) are arbitrary, we have
\[
\gamma = \bar{\gamma}^x (E, \theta) = -\frac{\partial \psi^x}{\partial \theta} (E_n, \theta).
\]

Exercise 7.2.4. Let \( \alpha, \beta, \gamma \) be real. Prove that
\[
\beta x + \gamma \geq 0 \quad \forall \alpha \quad \Rightarrow \beta = 0.
\]

Now write the remaining portion of the dissipation inequality...
\[
\mathbf{w} \left\{ \mathbf{I}^x_\mathbf{x} (E^*, \theta^*, g^*) - \mathbf{I}_\mathbf{x}^* \left[ \frac{\partial \mathbf{I}^x_\mathbf{x}}{\partial E^*} (E^*, \theta^*) \right] \mathbf{I}_\mathbf{x}^* \right\} + f_3 \left( x, E^*, \theta^*, g^* \right) = 0.
\]

This can hold \( \forall \mathbf{I}_x^* \) iff \( \mathbf{I}^x_\mathbf{x} (E^*, \theta^*, g^*) - \mathbf{I}_\mathbf{x}^* \left[ \frac{\partial \mathbf{I}^x_\mathbf{x}}{\partial E^*} (E^*, \theta^*) \right] \mathbf{I}_\mathbf{x}^* = 0 \). By the arbitrariness of \( x^*, E^*, \theta^*, \) and \( g^* \), we have
\[
\mathbf{I} = \mathbf{I}^x_\mathbf{x} (E^*, \theta^*) = \mathbf{I}_\mathbf{x}^* \left[ \frac{\partial \mathbf{I}^x_\mathbf{x}}{\partial E^*} (E^*, \theta^*) \right] \frac{\mathbf{I}^x_\mathbf{x}}{\mathbf{I}_\mathbf{x}^*}.
\]

**Exercise 7.2.5.** Let \( \mathbf{A}, \mathbf{B} \in \mathbf{V}(\mathbf{L}_x^*) \) and let \( \alpha \) be real. Prove that
\[
\mathbf{w} (\mathbf{B} \mathbf{A}) + \alpha = 0 \quad \forall \mathbf{A} \Rightarrow \mathbf{B} = 0.
\]

Finally, the dissipation inequality has been reduced to
\[
\int_\mathbf{x}^* \mathbf{r}^x_\mathbf{x} (E^*, \theta^*, g^*) \cdot \mathbf{g}^* = 0.
\]
Since \( x^*, E^*, \theta^*, \) and \( g^* \) are arbitrary, we can write
\[
\mathbf{r}^x_\mathbf{x} (E^*, \theta^*, g^*) \cdot \mathbf{g}^* = 0. \quad \Box
\]

We could make considerably more general constitutive assumptions for thermoelectrivity as far as dependence on strain type quantities is concerned and still get conditions...
(i)–(iii). However, condition (iv) would be more complicated.

According to the heat conduction inequality,

\[ q \cdot g = |q| |g| \cos(q, g) \leq 0 \]

\[ \Rightarrow \cos(q, g) = 0 \]

\[ \Rightarrow -\pi/2 \leq \theta(q, g) \leq +\pi/2 \]

except in degenerate cases where \( q \cdot g = 0 \). Since \( q = \nabla T \) points in the direction of increasing temperature and since \( g \) measures the rate of heat flow into a point, we can interpret the heat conduction inequality as implying that heat flows from hot to cold. This result may be demonstrated by arbitrarily choosing \( X \) and \( t \) and then choosing a point \( \mathbf{P} \) whose surface at time \( t \) passes through \( q \) and has a unit outer normal \( \mathbf{n} \) that parallels \( \theta(q, g) \). Then

\[ \frac{\partial q}{\partial t} = q \cdot \mathbf{n} = \frac{q}{|q|} \cdot \frac{\partial q}{\partial t} \geq 0 \]

---

\(^{2}\)Of course here we are only considering heat flow due to conduction and only thermoelastic bodies.
and we conclude that positive heat flows into $\mathcal{C}$.

As another interesting implication of the heat conduction inequality, we have

**Theorem 7.2.3.** If the heat conduction inequality holds, then

$$\varphi = 0 \Rightarrow \varphi = 0 ;$$

i.e., no temperature gradient means no heat flow (due to conduction). (Shrink by itself will not cause net flow in electric bodies.)

**Proof.** For fixed $E_0$ and $\varphi$ define the function $\varphi$ through

$$\varphi(q) = q \cdot \nabla \mathcal{U}(E_0, \varphi, \varphi).$$

By the heat conduction inequality, $\varphi$ has a minimum at $0$ since

$$\varphi(q) \leq 0 = \varphi(q).$$

---

\[ \varphi = \nabla \varphi(x) = \overline{\varphi_x}(E_x, \Theta, x). \]

Conditions (i)-(iii) also have a number of interesting consequences. For example, they allow us to write

\[ \psi = \tau \left( \frac{\partial \Phi_x}{\partial E_x} E_T \right) + \frac{\partial \Phi_x}{\partial \Theta} \Theta \]

\[ = \tau \left( \left( \frac{\partial \Phi_x}{\partial E_x} E_T \right) L_m \right) + \frac{\partial \Phi_x}{\partial \Theta} \Theta \]

\[ = \frac{1}{\rho} \tau \left( I L_T \right) - \gamma \Theta. \]

But from \( \psi = \varepsilon - \Theta \eta \), we get

\[ \varepsilon = \psi + \gamma \Theta + \eta \Theta; \]

and

\[ \rho \varepsilon = \tau \left( I L_T \right) + \Theta \rho \eta. \]

Substitution of this result into the energy equation leads to

Exercise 7.2.6. Show that \( \nabla \varphi(x) = \Phi_x(E_x, \Theta, x) \).

2 C.f., the analysis on p. 7.2.3.

3 Theorem 6.3.3.
Theorem 7.2.4. In thermoelasticity, the energy equation can be written in the form

\[ \nabla \cdot \mathbf{\dot{q}} + \rho \mathbf{r} = \rho \mathbf{\theta} \mathbf{\dot{\theta}}. \]

As immediate corollaries, we have

Theorem 7.2.5. In thermoelasticity, a process is locally adiabatic \(^2\) if it is isentropic \((\dot{\mathbf{r}} = 0)\).

Proof. Exercise 7.2.7. \(\square\)

Theorem 7.2.6. In thermoelasticity and for an insulated body \((\mathbf{q} = 0 \text{ and } \mathbf{B}_t \text{ and } r = 0)\),

\[ \frac{d}{dt} \iiint \rho \mathbf{\dot{\theta}} \, dx = \iiint \frac{\mathbf{\nabla} \cdot \mathbf{\dot{q}}}{\rho} \, dx \leq 0. \]

Thus, the total entropy of an insulated body does not decrease.

Proof. Exercise 7.2.8. \(\square\)

We started out assuming that \(\mathbf{\dot{q}}\) was smooth, but

\[ \text{Note that this is the inequality of Exercise 6.3.1!} \]

with equality holding, (as functional minima in various norms exist). \(\text{See Exercise 6.3.5.}\)
(i)–(iii) together with the smoothness assumptions on \( \overline{T}^x \) and \( \overline{F}^x \) actually imply that \( \overline{T}^x \) is two times continuously differentiable. Therefore,

\[
\frac{\partial}{\partial \theta} \frac{\partial}{\partial x} \overline{T}^x (F, \theta) = \frac{\partial}{\partial x} \frac{\partial}{\partial \theta} \overline{T}^x (F, \theta).
\]

Substitution of the stress and entropy relations into this equation yields

**Theorem 7.2.7.** In thermoelasticity, the response functions for stress and entropy satisfy the Maxwell relation

\[
\frac{\partial}{\partial \theta} \left[ \frac{1}{\rho} \overline{F}^x (E, \theta) (F^T)^{-1} \right] = -\frac{\partial}{\partial x} \overline{F}^x (E, \theta).
\]

**Supplementary Reading**

Same as for § 7.1
7.3. Entropy as the Independent Thermodynamical Variable

Suppose that we can invert the relation

\[ \eta = \eta_x(F, \theta) \]

w.r.t. \( \theta \) so as to write

\[ \theta = \theta_x(F, \eta) \].

Of course, we want the function \( \theta_x \) to be smooth in \( F \) and \( \eta \). We know from calculus that this smooth inversion is possible if

\[ \frac{d\eta_x}{d\theta}(F, \theta) \neq 0. \]

**Definition 7.3.1.** The scalar

\[ c = c_x(F, \theta) = \theta \frac{d\eta_x}{d\theta}(F, \theta) \]

is the specific heat (at fixed strain).

Thus, our earlier remarks may be formalized as

**Theorem 7.3.1.** A necessary and sufficient condition for the smooth invertibility of \( \eta = \eta_x(F, \theta) \) w.r.t. \( \theta \) is that the specific heat not vanish.

We can obtain some physical feeling for the specific heat by considering
\[ \varepsilon = \psi + \theta \gamma \]  

Differentiation w.r.t. \( \theta \) yields

\[ \frac{\partial \varepsilon}{\partial \theta} = \frac{\partial \psi}{\partial \theta} + \gamma + \theta \frac{\partial \gamma}{\partial \theta} = c \]

in light of the entropy relation \(^2\) and Definition 7.3.1. Hence, we have

**Theorem 7.3.2.** Write

\[ \varepsilon = \overline{\varepsilon}^x(F_n, \theta) + \theta \overline{\gamma}^x(F_n, \theta) = \overline{\varepsilon}^x(F_n, \theta). \]

Then

\[ c = \frac{\partial \overline{\varepsilon}^x(F_n, \theta)}{\partial \theta}. \]

Thus, the specific heat is the rate of change of the specific internal energy w.r.t. temperature (at fixed strain).

This last remark makes it quite plausible to assume that the specific heat does not vanish, and we make this assumption for the remainder of this section. Then we can write

\[ \theta = \overline{\varepsilon}^x(F_n, \gamma). \]

---

\(^1\) Definition 6.3.1.

\(^2\) Theorem 7.2.2.
and from \( \Psi = \varepsilon - \eta \) we get
\[
\varepsilon = \Psi^x (E_n, \Theta^x (E_n, \eta)) + \eta \Theta^x (E_n, \eta) = \Xi^x (E_n, \eta).
\]

Differentiation w.r.t. \( \eta \) yields
\[
\frac{\partial \Xi^x (E_n, \eta)}{\partial \eta} = \frac{\partial \Psi^x (E_n, \Theta^x (E_n, \eta))}{\partial \eta} \frac{\partial \Theta^x (E_n, \eta)}{\partial \eta} + \Xi^x (E_n, \eta) + \eta \frac{\partial \Xi^x (E_n, \eta)}{\partial \eta}.
\]

But
\[
\frac{\partial \Psi^x (E_n, \Theta^x (E_n, \eta))}{\partial \theta} = -\eta
\]

by the entropy relation. Therefore, we have
\[
\Theta = \Theta^x (E_n, \eta) = \frac{\partial \Xi^x (E_n, \eta)}{\partial \eta}.
\]

In the same manner differentiation w.r.t. \( E_n \) leads to
\[
\frac{\partial \Xi^x (E_n, \eta)}{\partial E_n} = \frac{\partial \Psi^x (E_n, \Theta^x (E_n, \eta))}{\partial E_n},
\]

and hence
\[
I = \rho \frac{\partial \Xi^x (E_n, \eta)}{\partial E_n} E_n^T = \Xi^x (E_n, \eta).
\]
Therefore, we have established

Theorem 7.3.3. Let the hypotheses of Theorem 7.2.2 hold and suppose that \( c \neq 0 \). Then

\[ \mathbf{e} = \mathbf{E}^x (F_n, \eta) \]  

and

\[ \theta = \mathbf{E}^x (F_n, \eta) = \frac{\partial \mathbf{E}^x}{\partial \eta} (F_n, \eta) \quad \text{--- the temperature relation}, \]

and

\[ \mathcal{I} = \mathbf{F}^x (F_n, \eta) = \mathbf{F} \frac{\partial \mathbf{E}^x}{\partial F_n} (F_n, \eta) F_n^T \quad \text{--- the alternative stress relation}. \]

Of course, we would have come out with these last two relations for the constitutive equations for temperature and stress if we had started out very beginning with \( \eta \) rather than \( \theta \) as the thermodynamical independent variable.

Supplementary Reading

Same as for § 7.1

\( \mathbf{e} \) as independent variable

Legendre transformation approach
7.4. Consequences of Material Indifference

The principle of material indifference requires that the response functions of Theorem 7.2.2 meet

\[ \bar{T}^x (\Omega E, \theta) = \Omega \bar{T}^x (E, \theta) \Omega^T, \]
\[ \bar{\Phi}^x (\Omega E, \theta) = \Phi^x (E, \theta), \]
\[ \bar{\Psi}^x (\Omega E, \theta) = \Psi^x (E, \theta), \]
\[ \bar{\varphi}^x (\Omega E, \theta, \varphi) = \Omega \varphi^x (E, \theta, \varphi) \]

A. invertible \( E \), \( \Psi \) positive \( \theta \), \( \forall \varphi \), and \( \forall \) orthogonal \( \Omega \). The transformation laws for \( \bar{T} \) and \( \bar{E} \) were developed in § 3.2. The fields \( \bar{\Phi} \), \( \bar{\Psi} \), and \( \bar{\varphi} \) transform into themselves since they are scalars. The transformation laws for \( \bar{\Phi} \) and \( \bar{\Psi} \) are considered below.

To see how \( \bar{\varphi} \) transforms, we consider

\[ \bar{\varphi} = \varphi \cdot \Omega. \]

Since \( \varphi \) is a scalar, we assume that

\[ \bar{\varphi}^x = \varphi. \]

\( ^{1} \) See § 3.2,
Then since \( \vec{\xi} = Q \vec{x} \),

\[
\vec{g} \cdot \vec{\xi} = \vec{\xi} \cdot Q \vec{g} = (Q^T \vec{\xi}) \cdot \vec{g}.
\]

And because this holds for unit vectors \( \vec{g} \),

\[
\vec{g} = Q^T \vec{\xi} \iff \vec{\xi} = Q \vec{g}.
\]

The transformation law for \( \vec{g} \) is most clearly derived through the relation

\[
\nabla \vec{\xi}_x(x, t) = F^T_x(x, t) \vec{g}_x(x, t).
\]

For the equivalent “stained” motion, we would have

\[
\nabla \vec{\xi}_x(x, t) = \vec{E}_x(x, t) \vec{g}_x(x, t).
\]

But \( \vec{E}_x = \vec{F}_x \), and we have already seen that \( \vec{E}_x = Q \vec{F}_x \).

Therefore,

\[
\nabla \vec{\xi}_x = (Q \vec{F}_x)^T \vec{\xi}_x = F^T_x Q^T \vec{\xi}_x.
\]

---

1. See p. 3.2.5.
2. Definition 1.10.1.
3. Theorem 1.13.2.
4. Exercise 7.1.1.
5. See p. 3.2.8.
6. Theorem 1.10.2.
But we started with $\Theta x = F x^T g x$, whence

$$g = Q^T \dot{g} \iff \dot{g} = Q g.$$

Turning now to the response functions, we first consider the free energy. We assume that material indifference holds so that

$$\Psi^x_x(Q; E, \Theta) = \Psi^x_x(E, \Theta).$$

We make the usual polar decomposition $E = R U$, and choose $Q = R^T$ to set

$$\Psi^x_x(E; \Theta) = \Psi^x_x(R^T R U; \Theta) = \Psi^x_x(U; \Theta) = \Psi^x_x(Q; \Theta).$$

Conversely, the constitutive equation

$$\psi = \Psi^x_x(Q; \psi)$$

obviously satisfies the principle of material indifference because $\Theta = \Theta^*$ and $Q_x = \dot{C}_x^*.$

By the entropy relation, $^4$

---

$^1$ Theorem 2.6.1.

$^2$ C.f., the argument on p. 3.2.11.

$^3$ See p. 3.2.13.

$^4$ Theorem 7.2.2.
\[ \eta = \overline{\Psi}_n^x (F_n, \theta) = -\frac{\partial \overline{\Psi}_n^x (F_n, \theta)}{\partial \theta} = -\frac{\partial \overline{\Psi}_n^x (C_n, \theta)}{\partial \theta}; \]

and this reduced form is easily seen to satisfy material indifference.

By the stress relation,\(^1\)

\[ I = I_n^x (F_n, \theta) = \rho \frac{\partial \overline{\Psi}_n^x (F_n, \theta)}{\partial F_n} F_n^T = \rho \frac{\partial \overline{\Psi}_n^x (C_n, \theta)}{\partial F_n} F_n^T. \]

We fall back on components relative to an orthonormal basis to calculate \( \frac{\partial \overline{\Psi}_n^x (C_n, \theta)}{\partial F_n} \).\(^2\)

\[ (\frac{\partial \overline{\Psi}_n^x}{\partial F_n})^\langle ij \rangle = \frac{\partial \overline{\Psi}_n^x}{\partial F_n^\langle ij \rangle} = \frac{\partial \overline{\Psi}_n^x}{\partial C_n^{\langle mn \rangle}} \frac{\partial C_n^{\langle mn \rangle}}{\partial F_n^\langle ij \rangle}. \]

Since \( C_n^{\langle mn \rangle} = F_n^{\langle en \rangle} F_n^{\langle en \rangle} \),\(^3\)

(and here we sum on all repeated indices)

---

\(^1\) Theorem 7.2.2,

\(^2\) See p. 7.2.3,

\(^3\) Exercise 2.6.3, Theorem 1.10.5, Theorem 1.9.3.
\[ \frac{\partial C_{x}^{<mn>}}{\partial F_{x}^{<ij>}} = \frac{\partial F_{x}^{<lm>}}{\partial F_{x}^{<ij>}} F_{x}^{<ln>} + F_{x}^{<lm>} \frac{\partial F_{x}^{<ln>}}{\partial F_{x}^{<ij>}} \]

\[ = \delta_{li} \delta_{mj} F_{x}^{<lm>} + F_{x}^{<lm>} \delta_{ki} \delta_{nj} \]

\[ = \delta_{mj} F_{x}^{<in>} + \delta_{nj} F_{x}^{<im>} . \]

Thus,

\[ (\frac{\partial \bar{\psi}_{x}^{x}}{\partial F_{x}^{<ij>}}) = \frac{\partial \bar{\psi}_{x}^{x}}{\partial C_{x}^{<mn>}} (\delta_{mj} F_{x}^{<in>} + \delta_{nj} F_{x}^{<im>} ) \]

\[ = \frac{\partial \bar{\psi}_{x}^{x}}{\partial C_{x}^{<in>}} F_{x}^{<in>} + \frac{\partial \bar{\psi}_{x}^{x}}{\partial C_{x}^{<mj>}} F_{x}^{<jm>} , \]

or

\[ \frac{\partial \bar{\psi}_{x}^{x}}{\partial F_{x}^{<ij>}} = F_{x} (\frac{\partial \bar{\psi}_{x}^{x}}{\partial C_{x}^{<in>}}) + F_{x} \frac{\partial \bar{\psi}_{x}^{x}}{\partial C_{x}^{<mj>}} . \]

Then the stress relation becomes

\[ I = \bar{F}_{x} (F_{x}, \Theta) = \rho F_{x} \left[ \frac{\partial \bar{\psi}_{x}^{x}}{\partial C_{x}^{<in>}} + (\frac{\partial \bar{\psi}_{x}^{x}}{\partial C_{x}^{<in>}})^{T} \right] \bar{C}_{x}^{<in>}. \]

Since \( C_{x} \) is symmetric,

\[ (\frac{\partial \bar{\psi}_{x}^{x}}{\partial C_{x}^{<in>}})^{T} = \frac{\partial \bar{\psi}_{x}^{x}}{\partial C_{x}^{<in>}} . \]

(Components-wise, we agree to view \( \bar{\psi}_{x}^{x} \) as a function of
the six independent components \( \{ \gamma_{ij} \} \). Hence,

\[
I = I^x_n (E_m, \theta) = 2 \rho E_m \frac{\partial \bar{\Psi}^x}{\partial E_n} (\gamma_{ij}, \theta) F^T \n.
\]

In order to demonstrate that this reduced stress relation satisfies material indifference, consider

\[
\bar{\Psi}^x (Q E, \theta) = 2 \rho (Q E) \frac{\partial \bar{\Psi}^x}{\partial \xi} (\gamma_{ij}, \theta) (Q E)^T
\]

\[
= \mathbb{Q} [2 \rho E \frac{\partial \bar{\Psi}^x}{\partial \xi} (\gamma_{ij}) E^T] Q^T
\]

\[
= \mathbb{Q} I^x_n (E, \theta) Q^T.
\]

Finally, we consider the heat flux. Assume that material indifference is satisfied so that

\[
\bar{Q}^x_n (E, \theta, g) = \mathbb{Q}^T \bar{Q}^x_n (Q E, \theta, \mathbb{Q} g).
\]

We chose \( \mathbb{Q} = \mathbb{R}^T \) \((E = \mathbb{R} U)\) to get

\[
\bar{Q}^x_n (E, \theta, g) = \mathbb{R} \bar{Q}^x_n (U, \theta, \mathbb{R}^T g)
\]

\[
= EU^{-1} \bar{Q}^x_n (U, \theta, U^T g)
\]

\[
= F \bar{Q}^x_n (\zeta, \theta, F g).
\]

\[\text{See pp. 5.1.3 and 5.1.4 for the indifference of } \rho.\]
Conversely, suppose that
\[
\widecheck{\mathbf{F}}^x \mathbf{(F, \theta, \mathbf{g})} = \mathbf{E} \widecheck{\mathbf{F}}^x \mathbf{(C, \theta, \mathbf{E}^T \mathbf{g})}.
\]
Then
\[
\widecheck{\mathbf{F}}^x \mathbf{(QF, \theta, \mathbf{g})} = \mathbf{Q} \mathbf{E} \widecheck{\mathbf{F}}^x \mathbf{(C, \theta, \mathbf{E}^T \mathbf{Qg})} = \mathbf{Q} \mathbf{E} \widecheck{\mathbf{F}}^x \mathbf{(C, \theta, \mathbf{E}^T \mathbf{g})} = \mathbf{Q} \widecheck{\mathbf{F}}^x \mathbf{(E, \theta, \mathbf{g})},
\]
and material indifference is satisfied.

From Exercise 7.1.1, \( \mathbf{E} \mathbf{F}^T \mathbf{g} = \mathbf{Q} \mathbf{E} \mathbf{F} \mathbf{g} \); and \( \therefore \) we can write the reduced constitutive equation for the heat flux in the more convenient form
\[
\mathbf{f} = \mathbf{E} \widecheck{\mathbf{F}}^x \mathbf{(Cw, \theta_w, \mathbf{Q}\theta_w)}.
\]
These results can be summarized as

**Theorem 7.4.1.** The constitutive equations obtained in Theorem 7.2.2 meet the principle of material indifference if they assume the reduced forms
\[
\psi = \widecheck{\mathbf{F}}^x \mathbf{(Cw, \theta)}, \\
\gamma = -\frac{\partial \psi}{\partial \theta} \mathbf{(Cw, \theta)},
\]
\[ I = 2\rho \bar{E}_n \frac{\partial \bar{\Psi}_x}{\partial \bar{C}_n} \bar{E}_n^T, \]

\[ q = \bar{E}_n \bar{\Psi}_x (\bar{C}_n, \Theta, V\Theta_n). \]

Exercise 7.4.1 Show that the heat conduction inequality of Theorem 7.2.2 reduces to

\[ \bar{\Psi}_x (\bar{C}_n, \Theta, V\Theta_n) \cdot V\Theta_n \geq 0. \]

It is interesting to note that

\[ I = 2\rho \bar{E}_n \frac{\partial \bar{\Psi}_x}{\partial \bar{C}_n} \bar{E}_n^T \]

is automatically symmetric. Thus, we have

\[ \text{Theorem 7.4.2. In thermoclasticity, balance of angular momentum is a consequence of balance of linear momentum, the two laws of thermomechanics, and the principle of material indifference.} \]

Supplementary Reading

Same as for § 7.1

\[ \text{Cf., Theorem 2.11.4.} \]

\[ \text{Cf., footnote on p. 7.1.2.} \]

\[ \text{Cf., footnote on p. 7.1.2.} \]
7.5. Material Symmetry. Isotropy

We begin by writing the constitutive equations of thermoelectricity in the form:

\[ I = T^X (E_n, \theta) \]
\[ \psi = T^X (E_n, \theta) \]
\[ \gamma = T^X (E_n, \theta) \]
\[ \eta = T^X (E_n, \theta, g) \]

In §3.4, we introduced the notion of symmetry group to study the symmetry of the stress response. Here we must also consider the geometries of the free energy response, the entropy response, and the heat flux response. Following §3.4 and noting that \( \theta \) and \( g \) are independent of the reference configuration, we have

**Definition 7.5.1.** The symmetry group of the stress response w.r.t. the reference configuration \( \Sigma_n \), the symmetry group of the free energy response w.r.t. the reference configuration \( \Sigma_n \), etc. are defined by

\[ \Sigma_n^X (\Sigma_n) = \{ H | H \in U, T^X (E^H_n, \theta) = T^X (E_n, \theta) \forall E, \theta \} \]

*See Theorem 7.2.2.*
\[ \mathcal{D}_x(\psi) = \{ H \mid H \in U, \overline{\mathcal{D}}_n(\Phi_H, \Theta) = \overline{\mathcal{D}}_n(\Theta, \Theta) \forall E, \Theta \}, \]
\[ \mathcal{D}_n(\psi) = \{ H \mid H \in U, \overline{\mathcal{D}}_n(\Phi_H, \Theta) = \overline{\mathcal{D}}_n(\Theta, \Theta) \forall E, \Theta \}, \]
\[ \mathcal{D}_n(\varphi) = \{ H \mid H \in U, \overline{\mathcal{D}}_n(\Phi_H, \Theta, \varphi) = \overline{\mathcal{D}}_n(\Theta, \Theta, \varphi) \forall E, \Theta, \varphi \}, \]

respectively.

As in Theorem 3.4.1, each of the above groups really is a group w.r.t. tensor multiplication.

**Definition 7.5.2.** The complete symmetry group \( \mathcal{D}_n \), (with respect to the reference configuration \( \mathcal{D}_n \)), is the intersection of the separate symmetry groups:

\[ \mathcal{D}_n = \mathcal{D}_n(\zeta) \cap \mathcal{D}_n(\psi) \cap \mathcal{D}_n(\eta) \cap \mathcal{D}_n(\varphi), \]

We apply Noll's classification\(^2\) to the complete symmetry group. Thus

**Definition 7.5.3.** Isotropy, fluidity, and solidity of a thermodynamic material are defined by

<table>
<thead>
<tr>
<th>Property</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>isotropic</td>
<td>( \mathcal{D}_n = \emptyset ); (( \zeta ) is undistorted)</td>
</tr>
<tr>
<td>fluid</td>
<td>( \mathcal{D}_n = \mathcal{U} ); (( \zeta ) is fluid)</td>
</tr>
<tr>
<td>solid</td>
<td>( \mathcal{D}_n \subset \mathcal{U} ); (( \zeta ) is solid)</td>
</tr>
</tbody>
</table>

\(^2\) Of course, in these definitions \( \mathcal{U} \) is restricted to be invertible and \( \Theta \) must be strictly positive.

\(^{2}\) Definitions 3.4.2 - 3.4.4.
Orthogonal members of the symmetric groups satisfy more familiar conditions.

**Theorem 7.5.1.** Let \( Q \in \mathcal{O} \). Then \( Q \in \mathcal{D}_n^x(\Gamma) \) iff

\[
\bar{\Phi}^x(Q \cdot F \cdot Q^T, \theta) = \bar{\Phi}^x(F, \theta) Q^T \quad \forall F, \theta.
\]

**Proof.** This theorem is a special case of Theorem 3.4.3. \( \Box \)

We note that if \( Q \in \mathcal{D}_n^x(\Gamma) \), then by Theorem 7.5.1

\[
-Q \in \mathcal{D}_n^x(\Gamma).
\]

Thus, \( \mathcal{D}_n^x(\Gamma) \) can contain improper orthogonal tensors; indeed, it always contains \(-\mathbf{I}\).

**Theorem 7.5.2.** Let \( Q \in \mathcal{O} \). Then \( Q \in \mathcal{D}_n^x(\Psi) \) iff

\[
\bar{\Phi}^x(Q \cdot F \cdot Q^T, \theta) = \bar{\Phi}^x(F, \theta) \quad \forall F, \theta.
\]

An identical result holds for \( \mathcal{S}_n^x(\eta) \).

**Proof.** Suppose \( Q \in \mathcal{D}_n^x(\Psi) \). Then

\[
\bar{\Phi}^x(F \cdot Q, \theta) = \bar{\Phi}^x(F, \theta) \quad \forall F, \theta.
\]

Since this must hold \( \forall F \), it holds when \( F \) above is replaced by \( Q \cdot F \cdot Q^T \). Therefore,

\[
\bar{\Phi}^x(Q \cdot F \cdot Q^T, \theta) = \bar{\Phi}^x(Q \cdot F \cdot Q^T, \theta) \quad \forall F, \theta;
\]

or

\[
\bar{\Phi}^x(Q \cdot F, \theta) = \bar{\Phi}^x(Q \cdot F \cdot Q^T, \theta) \quad \forall F, \theta.
\]
But by material indifference,
\[ \bar{\Phi}_n^x (QF, \theta) = \bar{\Phi}_n^x (E, \theta); \]
and so
\[ \bar{\Phi}_n^x (QFQ^T, \theta) = \bar{\Phi}_n^x (E, \theta) \forall E, \theta. \]

Conversely, suppose that
\[ \bar{\Phi}_n^x (QFQ^T, \theta) = \bar{\Phi}_n^x (E, \theta) \forall E, \theta. \]
Then by material indifference
\[ \bar{\Phi}_n^x (QFQ^T, \theta) = \bar{\Phi}_n^x (QF, \theta) \forall E, \theta. \]
Replace \( E \) by \( Q^T E \) to get — poor choice — see next theorem:
\[ \bar{\Phi}_n^x (EQ, \theta) = \bar{\Phi}_n^x (E, \theta) \forall E, \theta. \]
Therefore, \( Q^T \in \mathcal{X}_n^x (\Psi) \). But by one of the group axioms
\[ (Q^T)^{-1} = Q \in \mathcal{X}_n^x (\Psi), \]
We note again that \( Q \in \mathcal{X}_n^x (\Psi) \Rightarrow -Q \in \mathcal{X}_n^x (\Psi) \).

**Theorem 7.5.3.** Let \( Q \in \Theta_1 \). Then \( Q \in \mathcal{X}_n^x (\Psi) \) if

1. See p. 7.4.1
2. \( (G_3) \) of Definition 113.3.
\( \overline{q}^x(QFQ^T, \theta, Qg) = \overline{q}^x(E, \theta, g) \lor E, Qg. \)

**Proof.** Suppose \( Q \in D^x_n(g) \). Then

\[ \overline{q}^x(EQ, \theta, Qg) = \overline{q}^x(E, \theta, g) \lor E, Qg. \]

Since this must hold \( \forall E \) and \( g \), we can replace them by \( QFQ^T \) and \( Qg \), respectively, to get

\[ \overline{q}^x(QF, \theta, Qg) = \overline{q}^x(QFQ^T, \theta, Qg) \lor E, Qg. \]

But by material midiffERENCE,

\[ \overline{q}^x(QF, \theta, Qg) = \overline{q}^x(E, \theta, g), \]

so that

\[ \overline{q}^x(QFQ^T, \theta, Qg) = \overline{q}^x(E, \theta, g) \lor E, Qg. \]

Conversely, suppose that

\[ \overline{q}^x(QFQ^T, \theta, Qg) = \overline{q}^x(E, \theta, g) \lor E, Qg. \]

Then by material midiffERENCE,

\[ \overline{q}^x(QFQ^T, \theta, Qg) = \overline{q}^x(QF, \theta, Qg) \lor E, Qg. \]

Since this holds \( \forall E \) and \( g \), we can write

\[ \overline{q}^x(Q(Q^T) Q^T, \theta, Q(\overline{Q})g) = \overline{q}^x(Q(Q^T) Q, \theta, Q(\overline{Q})g), \]
\( \overline{q}_x^x(E, \theta, g) = \overline{q}_x(E, \theta, g) \).

Thus, \( q \in \mathcal{X}_x(q) \).

In contract with our results concerning the symmetry groups for \( I, \psi, \) and \( \gamma \), we note that we evidently cannot conclude from Theorem 7.5.3 that if \( q \in \mathcal{X}_x(q) \) then \( -q \in \mathcal{X}_x(q) \). This is apparently due to the fact that \( I, \psi \) in \( \gamma \) are even-order tensors while \( q \) is an odd-order tensor.

One of the consequences of the heat conduction inequality was \( \overline{q}_x^x(E, \theta, 0) = 0 \). According to the next theorem, if \( -I \in \mathcal{X}_x(q) \), then we have this result without recourse to the second law.

**Theorem 7.5.4.** If \(-I \in \mathcal{X}_x(q)\), then

\[ \overline{q}_x^x(E, \theta, 0) = 0. \]

**Proof.** By Theorem 7.5.3, \(-I \in \mathcal{X}_x(q) \) implies

\[ \overline{q}_x^x(E, \theta, -g) = -
\overline{q}_x^x(E, \theta, g). \]

Choosing \( g = 0 \) yields the desired result. \( \Box \)

---

**Theorem 7.2.3.**
While we have used material indifference in our study of
the orthogonal elements of the symmetry groups, we have
not made use of the reduced constitutive equations of
Theorem 7.4.1 which take into account the principle
of material indifference one and for all.

By Theorem 7.4.1, we can write
\[ \overline{\mathbf{x}}(E_n, \theta) = E_n \overline{\mathbf{x}}(E_n, \theta) E_n^T \]
\[ = E_n \overline{\mathbf{x}}(E E_n, \theta) E_n. \]

Suppose \( H \in \mathbf{S}^n(1) \). Then by Definition 7.5.1,
\[ \overline{\mathbf{x}}(E H, \theta) = \overline{\mathbf{x}}(E, \theta) \]
\[ \text{or} \quad E H \overline{\mathbf{x}}(H^{-1} E H, \theta) H^{-1} = E \overline{\mathbf{x}}(E E, \theta) E^T. \]
\[ \text{or} \quad H \overline{\mathbf{x}}(H^{-1} E H, \theta) H^{-1} = \overline{\mathbf{x}}(E, \theta). \]

Since all of the above steps are reversible, a unimodular
\( H \) which satisfies the last equation for \( \theta = 0 \) is in \( \mathbf{S}^n(1) \).

We can use Theorem 7.4.1 and Definition 7.5.1 on \( \mathbf{S}^n(4) \),
\( \mathbf{S}^n(\gamma) \), and \( \mathbf{S}^n(\varphi) \) in the same way.

First consider
\[ \overline{\mathbf{x}}(E_n, \theta) = \overline{\mathbf{x}}(E_n, \theta) = \overline{\mathbf{x}}(E_n^T E_n, \theta). \]

Suppose \( H \in \mathbf{S}^n(\gamma) \). Then
\[ \xi^x(E, \mathcal{F}, \varepsilon) = \xi^x(E, \varepsilon) \]
\[ \xi^x(H^{I,F}(H, \varepsilon)) = \xi^x(H, \varepsilon) \]
\[ \xi^x(H^{I,G}(H, \varepsilon)) = \xi^x(H, \varepsilon). \]

Conversely, if an element \( \xi \) which satisfies this equation \( \xi(E) = \xi(E) \) and \( \varepsilon = 0 \) in \( \mathcal{X}^x(\varepsilon) \), clearly, an identical result holds for \( \mathcal{X}^x(\varepsilon) \).

Finally, consider
\[ \xi^x(E, \mathcal{F}, \varepsilon) = E \xi^x(E, \mathcal{F}, \varepsilon) \]
\[ = E \xi^x(E, \mathcal{F}, \varepsilon) \]
\[ = E \xi^x(E, \mathcal{F}, \varepsilon) \]
\[ = E \xi^x(E, \mathcal{F}, \varepsilon). \]

Suppose \( H \in \mathcal{X}^x(\varepsilon) \). Then
\[ \xi^x(E, \mathcal{F}, \varepsilon) = \xi^x(E, \mathcal{F}, \varepsilon) \]
\[ E \xi^x(H^{I,F}(H, \varepsilon), H^{I,F}(H, \varepsilon)) = E \xi^x(H, H^{I,F}(H, \varepsilon)) \]
\[ E \xi^x(H^{I,G}(H, \varepsilon), H^{I,G}(H, \varepsilon)) = E \xi^x(H, H^{I,G}(H, \varepsilon)). \]

Conversely, an element \( \xi \) which satisfies this equation \( \xi(E) = \xi(E) \) and \( \varepsilon = 0 \) is in \( \mathcal{X}^x(\varepsilon) \).
We then have the result up to...
Theorem 7.5.5. Let \( \phi \in \mathbb{R}^n \). Then \( \phi \in \mathbb{R}^n \) if:

\[
\phi^T (H^2 p, \theta) \phi^T = \phi^T (\lambda, \theta),
\]

\[
\phi^T (H^2 q, \theta) = \phi^T (\lambda, \theta),
\]

\[
\phi^T (H^2 \theta, \theta) = \phi^T (\lambda, \theta),
\]

\[
\phi^T (H^2 (\phi, \eta, H^T \phi), \theta) = \phi^T (\lambda, \theta, \phi).
\]

\( \forall \phi, \lambda, \theta, \eta, \phi \).

Again orthogonal elements of \( \mathbb{R}^n \) satisfy simple

conditions.

Theorem 7.5.6. Let \( \phi \in \mathbb{R}^n \). Then \( \phi \in \mathbb{R}^n \) if:

\[
\phi^T (\phi, \theta) \phi^T = \phi^T (\lambda, \theta) \phi^T,
\]

\[
\phi^T (\theta, \phi, \theta) = \phi^T (\lambda, \theta),
\]

\[
\phi^T (\phi, \theta, \phi) = \phi^T (\lambda, \theta),
\]

\[
\frac{\phi^T (\phi, \theta, \phi) \phi^T}{\phi^T (\phi, \theta, \phi)} = \phi^T (\lambda, \theta, \phi).
\]

\( \forall \phi, \theta, \lambda, \phi \).

\( \square \)
Up to this point we have ignored the state and entropy relations in our study of symmetry. Since we derive $I$ and $\eta$ from $\Psi$, we would expect $\Omega^X(I)$ and $\Omega^X(\eta)$ to be related to $\Omega^X(\Psi)$.

By Theorem 7.1.2,

$$\tilde{T}^X(E, \theta) = \rho \frac{\partial \Psi^X}{\partial E}(E, \theta) E^T.$$

Suppose that $H = \Omega^X(I)$, then by Definition 7.5.1,

$$\tilde{T}^X(EH, \theta) = \tilde{T}^X(E, \theta) \forall \theta, E.$$

or

$$\rho \frac{\partial \Psi^X}{\partial \theta}(EH, \theta) H^T E^T = \rho \frac{\partial \Psi^X}{\partial E}(E, \theta) E^T.$$

Thus, it is easy to see (Exercise 7.5.1) that

$$\frac{\partial \Psi^X}{\partial \theta}(EH, \theta) H^T = \frac{\partial \Psi^X}{\partial E}(E, \theta).$$

and therefore

$$\frac{\partial}{\partial \theta} \left[ \tilde{T}^X(EH, \theta) - \tilde{T}^X(E, \theta) \right] = 0.$$

Thus, the quantity in brackets is the same $\forall E$. Evaluation at $E = 1$ yields...
\[ \overline{\Phi}^x(FH, \theta) - \overline{\Phi}^x(E, \theta) = \overline{\Phi}^x(H, \theta) - \overline{\Phi}^x(1, \theta). \]

Since all of the above steps are reversible, any unimodular \( H \) which satisfies this last equation is in \( \mathcal{M}_n^x(I) \). Hence, we have proved

**Theorem 7.5.7. (Trenchell)** Let \( H \in \mathcal{U} \). Then \( H \in \mathcal{D}_n^x(I) \) if

\[ \overline{\Phi}^x(FH, \theta) = \overline{\Phi}^x(E, \theta) + \overline{\Phi}^x(H, \theta) - \overline{\Phi}^x(1, \theta) \quad \forall \theta, \theta. \]

Trenchell's theorem has a number of important corollaries.

**Theorem 7.5.8.** \( \mathcal{D}_n^x(\psi) \subset \mathcal{D}_n^x(I) \).

**Proof.** Suppose \( H \in \mathcal{D}_n^x(\psi) \). Then by Definition 7.5.1,

\[ \overline{\Phi}^x(FH, \theta) = \overline{\Phi}^x(E, \theta) \quad \forall \theta, \theta, \]

in particular (choosing \( E = 1 \)),

\[ \overline{\Phi}^x(H, \theta) = \overline{\Phi}^x(1, \theta); \]

and

\[ \overline{\Phi}^x(FH, \theta) = \overline{\Phi}^x(E, \theta) + \overline{\Phi}^x(H, \theta) - \overline{\Phi}^x(1, \theta). \]

Consequently, \( H \in \mathcal{D}_n^x(I) \) by Theorem 7.5.7. Thus,

---

H ∈ δ_x^n(4) ⇒ H ∈ δ_x^n(I) or δ_x^n(ψ) ⊂ δ_x^n(I). □

Theorem 7.5.9. Let ψ ∈ O. Then

Q ∈ δ_x^n(I) ⇒ Q ∈ δ_x^n(ψ).

Proof. Suppose Q ∈ O and Q ∈ δ_x^n(I). Then by Theorem 7.5.7,

Ψ_x^n(FQ, θ) = Ψ_x^n(F, θ) + Ψ_x^n(Q, θ) - Ψ_x^n(I, θ).

But by material indifference,

Ψ_x^n(Q, θ) = Ψ_x^n(I, θ);

and so

Ψ_x^n(FQ, θ) = Ψ_x^n(F, θ) ⇒ Q ∈ δ_x^n(ψ). □

The implication in Theorem 7.5.9 obviously holds in the other direction by Theorem 7.5.8, and this leads to

Theorem 7.5.10. The orthogonal subsets of δ_x^n(I) and δ_x^n(ψ) are identical, i.e.,

δ_x^n(I) ∩ O = δ_x^n(ψ) ∩ O.

Proof. Suppose Q ∈ δ_x^n(I) ∩ O. Then Q ∈ δ_x^n(I) and Q ∈ O. Then by theorem 7.5.9, Q ∈ δ_x^n(ψ). Thus,

δ_x^n(I) ∩ O ⊂ δ_x^n(ψ) ∩ O.

*See p. 7.4.1.
On the other hand suppose that $Q \in \mathcal{D}^n_1(\psi) \cap \emptyset$. Then $Q \in \mathcal{D}^n_1(\psi)$ and $Q \in \emptyset$, and by Theorem 7.5.7, $Q \in \mathcal{D}^n_1(I)$. Thus, we also have

$$\mathcal{D}^n_1(\psi) \cap \emptyset = \mathcal{D}^n_1(I) \cap \emptyset;$$

and we conclude that

$$\mathcal{D}^n_1(\psi) \cap \emptyset = \mathcal{D}^n_1(I) \cap \emptyset. \quad \Box$$

The next three theorems indicate situations in which the symmetry groups for the stress and the free energy agree completely.

**Theorem 7.5.11.** If $\mathcal{D}^n_1(I) = \mathcal{U}$, then $\mathcal{D}^n_1(I) = \mathcal{D}^n_1(\psi)$.

**Proof.** Let $H \in \mathcal{D}^n_1(I)$. Then from the proof of Theorem 7.5.7, we have that

$$\frac{\partial}{\partial E} \left[ \bar{\Psi}^n_1(FH, \theta) - \bar{\Psi}^n_1(E, \theta) \right] = 0.$$

When $\mathcal{D}^n_1(I) = \mathcal{U}$, this must hold for any $H \in \mathcal{U}$. In particular, it must hold for $H = \left[ \det E \right]^{1/2} E^{-1}$. This choice yields

$$\frac{\partial}{\partial E} \left[ \bar{\Psi}^n_1(\det E^{1/2} E^{-1}, \theta) - \bar{\Psi}^n_1(E, \theta) \right] = 0.$$

Thus, the quantity in brackets is the same $\forall E$ and evaluation at $E = 1$ yields

$$\bar{\Psi}^n_1(E, \theta) = \bar{\Psi}^n_1(\det E^{1/2} E^{-1}, \theta) = \bar{\Psi}^n_1(\det E, \theta).$$

Clearly, with this structure for $\bar{\Psi}^n_1$,\textsuperscript{13}

\textsuperscript{13} Interestingly, this needs to be checked back from Truesdell's theorem.
\[ \Psi^x(E, \theta) = \Phi^x(E, \theta) \quad \forall E \in \mathcal{V} \]

Hence, \( E \in \mathcal{V} \implies E \in \mathcal{D}^x(\psi) \) or \( E \in \mathcal{D}^x(\eta) \). By definition, \( \mathcal{D}^x(\psi) \subseteq \mathcal{V} \), and hence, \( \mathcal{D}^x(\psi) = \mathcal{V} \).

In the purely mechanical case, an elastic material is said to be hyperelastic when the stress is derived from a scalar field \( \psi \) through the stress relation. Also, in the purely mechanical case, the condition \( \mathcal{D}^x(\psi) = \mathcal{V} \) is the definition of a fluid. Therefore, in the absence of thermal effects, Theorem 7.5.11 states that the symmetry groups for the stress and the free energy are both equal to the unimodular group for a hyperelastic fluid.

When thermal effects are included, we have shown to define fluid, solid, etc., in terms of the complete symmetry group. However, the above result for hyperelastic fluids still holds; and, in fact, it is more readily obtainable.

**Theorem 7.5.12.** If the body is fluid, then
\[ \mathcal{D}^x(I) = \mathcal{D}^x(\psi) = \mathcal{D}^x(\eta) = \mathcal{D}^x(q) = \mathcal{V} \]

**Proof.** For a fluid body,
\[ \mathcal{D}^x = \mathcal{D}^x(I) \cap \mathcal{D}^x(\psi) \cap \mathcal{D}^x(\eta) \cap \mathcal{D}^x(q) = \mathcal{V} \]

Thus, \( \mathcal{V} = \mathcal{D}^x(I) \); but by definition, \( \mathcal{D}^x(I) \subseteq \mathcal{V} \), \( \mathcal{D}^x(I) = \mathcal{V} \).

**Definition 7.5.3 (Noll's classification).**
\( \mathcal{I}_n^m(T) = U \). Similar remarks hold for the other separate symmetry groups. □

In the case of solids, there generally is not equality of the separate symmetry groups. However, we do have the following result.

**Theorem 7.5.13.** If \( \mathcal{I}_n^m(T) \subset \mathcal{O} \), then \( \mathcal{I}_n^m(T) = \mathcal{I}_n^m(T) \).

**Proof.** Suppose \( \mathcal{I}_n^m(T) \subset \mathcal{O} \). Then \( H \in \mathcal{I}_n^m(T) \Rightarrow H \in \mathcal{O} \), and by Theorem 7.5.9, \( H \in \mathcal{I}_n^m(T) \Rightarrow H \in \mathcal{O} \). Thus, \( \mathcal{I}_n^m(T) \subset \mathcal{I}_n^m(T) \). But by Theorem 7.5.8, \( \mathcal{I}_n^m(T) \subset \mathcal{I}_n^m(T) \); and \( \mathcal{I}_n^m(T) = \mathcal{I}_n^m(T) \). □

We note that \( \mathcal{I}_n^m(T) \subset \mathcal{O} \) defines a solid in the purely mechanical case, but in thermoelasticity we need the complete symmetry group \( \mathcal{I}_n^m \subset \mathcal{O} \) for a solid.

**Theorem 7.5.14.** A body is isotropic w.r.t. stress response \( (\mathcal{O} \in \mathcal{I}_n^m(T)) \) iff it is isotropic w.r.t. free energy response \( (\mathcal{O} \in \mathcal{I}_n^m(T)) \).

**Proof.** Suppose the body is isotropic w.r.t. stress response. Then \( \mathcal{O} \in \mathcal{I}_n^m(T) \), and since the orthogonal subsets of \( \mathcal{I}_n^m(T) \) and \( \mathcal{I}_n^m(T) \) agree by Theorem 7.5.10, \( \mathcal{O} \in \mathcal{I}_n^m(T) \). The same argument establishes the converse. □

This last theorem means that we can define isotropy of the stress response through either \( \mathcal{I}_n^m(T) \) or \( \mathcal{I}_n^m(T) \).
This is important because $\Phi^n(\psi)$ is much simpler to work with than $\Phi^n(\mathcal{I})$.

Next we consider the entropy relation. By Theorem 7.2.2,

$$\Phi^n(E_n, \theta) = -\frac{\partial \Phi^n}{\partial \theta}(E_n, \theta).$$

Suppose that $H \in \Theta^n(\mathcal{I})$. Then by Definition 7.5.1,

$$\Phi^n(E_n, \theta) = \Phi^n(E, \theta) \text{ } \forall \theta, \theta'$$

or

$$-\frac{\partial \Phi^n}{\partial \theta}(E_n, \theta) = -\frac{\partial \Phi^n}{\partial \theta}(E, \theta)$$

or

$$\frac{\partial}{\partial \theta} [ \Phi^n(E_n, \theta) - \Phi^n(E, \theta) ] = 0.$$  

Thus, the quantity in brackets is the same $\forall \theta$. Evaluation at $\theta = \theta_0$ yields

$$\Phi^n(E_n, \theta_0) - \Phi^n(E, \theta_0) = \Phi^n(E_n, \theta_0) - \Phi^n(E, \theta_0).$$

Since all of the above steps are reversible, any unimodular $H$ which satisfies this last equation is in $\Theta^n(\mathcal{I})$. Hence, we have

**Theorem 7.5.15.** (Austin and Williams') Let $H \in \Theta$.

---

Then $H \in \mathcal{D}_n^x(\eta)$ iff

$$\Psi_n^x(\mathcal{E}, \theta) = \Psi_n^x(F, \theta) + \Psi_n^x(F, \theta_0) - \Psi_n^x(F, \theta_0) \quad \forall F, \theta$$

for some $\theta_0 > 0$.

Justin and Williams' theorem does not have as many corollaries as Truesdell's, but we do have the next two results.

**Theorem 7.5.16.** $I_n^x(\psi) \subset I_n^x(\eta)$.

**Proof.** Exercise 7.5.2. □

**Theorem 7.5.17.** If a body is isotropic w.r.t. free energy response ($\Theta \subset I_n^x(\psi)$), then it is isotropic w.r.t. entropy response ($\Theta \subset \mathcal{D}_n^x(\eta)$).

**Proof.** Suppose the body is isotropic w.r.t. free energy response. Then by Theorem 7.5.16,

$$\Theta \subset I_n^x(\psi) \subset \mathcal{D}_n^x(\eta).$$

Since $\Theta \subset \mathcal{D}_n^x(\eta)$, the entropy response is isotropic. □

Next we suppose that the body is isotropic, and we determine the appropriate representation formulas for the response functions. Of course, if the body is isotropic, then
\[ \Theta \in \mathcal{X} = \mathcal{X}_m(1) \land \mathcal{X}_m(4) \land \mathcal{X}_m(\eta) \land \mathcal{X}_m(q) \]

\[ \iff \Theta \in \mathcal{X}_m(1), \Theta \in \mathcal{X}_m(4), \Theta \in \mathcal{X}_m(\eta), \Theta \in \mathcal{X}_m(q). \]

Thus, isotropy of the body requires that each of the separate responses be isotropic. By Theorems 7.5.14 and 7.5.17, isotropy of the free energy response ensures that the stress and entropy response are isotropic.

We begin then by assuming that the free energy response is isotropic, i.e., \( \Theta \in \mathcal{X}_m(4) \). By Theorem 7.5.6, we must have

\[ \Psi_x (\Theta^T, \Theta) = \Psi_x (\Theta, \Theta) \quad \forall \Theta \in \Theta, \]

Thus, \( \Psi_x \) is an isotropic scalar-valued function of one symmetric tensor (\( \Theta \) is carried along parametrically). We develop a representation for such functions in the proof of Theorem 4.2.1. The function \( \Psi_x \) must have the form

\[ \Psi_x (\Theta, \Theta) = \Phi_x (I_c, II_c, III_c, \Theta), \]

where \( I_c, II_c, III_c \) are the principal invariants of \( \Theta \).

For the stress relation, we need \( \frac{\partial \Psi_x}{\partial \Theta_x} \). In the present case,

\[ \text{See p. 4.27.} \]
\[ \frac{\partial \Psi^x}{\partial \xi_x} = \frac{\partial \Psi^y}{\partial \xi_y} \frac{\partial y}{\partial \xi_x} + \frac{\partial \Psi^z}{\partial \xi_z} \frac{\partial z}{\partial \xi_x} + \frac{\partial \Psi^{\xi}}{\partial \xi} \frac{\partial x}{\partial \xi_x} \]

by an obvious chain rule. It is easy to show using components (Exercise 7.5.3) \(^1\) that

\[ \frac{\partial I_c}{\partial \xi_y} = I_c, \]

\[ \frac{\partial \Pi_c}{\partial \xi_y} = I_c \frac{1}{1-C_w}, \]

\[ \frac{\partial \Pi_c}{\partial \xi_x} = \Pi_c C^{-1}_w. \]

Then the reduced stress relation \(^2\) becomes

\[ T = 2\mu F \left[ \frac{\partial \Psi^y}{\partial I_c} \frac{1}{I_c} + \frac{\partial \Psi^z}{\partial \Pi_c} (I_c \frac{1}{1-C_w}) + \frac{\partial \Psi^{\xi}}{\partial \Pi_c} \Pi_c C^{-1}_w \right] F^T. \]

Now, as on p. 4.2.9,

\[ F^T F = B, \]

\[ F^T C F = F^T F F^T F = B^2, \]

\[ F^T C^{-1} F^T = F^T (F^T F)^{-1} F^T = I; \]

\(^1\) Relative to an eigenvalue basis it is extra easy.

\(^2\) Theorem 7.4.1.
and also

\[ I_B = I_C, \quad I_B = I_C, \quad I_B = I_C. \]

This we are lead to:

**Theorem 7.5.18.** \( \mathbf{C} \equiv \mathbf{C}^x (\Psi) \), then

\[ \Psi = \mathbf{C}^x (I_B, I_B, I_B, \theta) \]

where \( I_B, I_B, \) and \( I_B \) are the fundamental invariants of \( \mathbf{C} \); and the stress and entropy relations become

\[ J = 2\rho \left[ \frac{\partial \mathbf{C}^x}{\partial I_B} \right] + \left( \frac{\partial \mathbf{C}^x}{\partial I_B} + I_B \frac{\partial \mathbf{C}^x}{\partial I_B} \right) E^2 - \frac{\partial \mathbf{C}^x}{\partial I_B} E^2 \]

and

\[ \eta = -\frac{\partial \mathbf{C}^x}{\partial \theta} \]

respectively.

Conversely, if the above relations hold for the body in isotropic with respect to free energy response, stress response, and entropy response.

**Proof.** Only the converse assertion has yet to be proved, and we leave this as Exercise 7.5.2. \( \square \)

**Exercise 7.5.5.** Use the Hamilton–Casley Theorem (Theorem

\[ \text{See Exercise 4.2.7.} \]
1.4.12) to put the above stress relation in the form

\[ I = 2\mu \left[ (\mathbb{I} \frac{\partial \mathbf{\varepsilon}}{\partial \mathbb{B}} + \frac{\mu}{\eta} \frac{\partial \mathbf{\gamma}}{\partial \mathbb{B}}) \mathbf{\varepsilon} + \frac{\mu}{\eta} \mathbf{\gamma} \cdot \mathbf{\varepsilon} - \frac{\mu}{\eta} \frac{\partial \mathbf{\gamma}}{\partial \mathbb{B}} \mathbf{\varepsilon} \right]. \]

Of course, in these stress relations we can always use the density equation

\[ \rho = \frac{1}{\sqrt{\mathbb{B}}} \rho^0, \]

to replace \( \rho \) by the density in the reference configuration \( \mathbb{B} \).

It still remains to investigate the heat flux. By Theorem 7.5.6 and Exercise 7.1.1, the heat flux response is isotropic if

\[ \bar{q}^x (\mathbf{C}, \mathbf{\varepsilon}, \mathbf{\gamma}) = \bar{q}^x (\mathbf{C}, \mathbf{\varepsilon}) \quad \forall \mathbf{\varepsilon}, \mathbf{\gamma}. \]

Thus, \( \bar{q}^x \) is an isotropic vector-valued function of one symmetric tensor and one vector, and hence it admits the representation

\[ \bar{q}^x (\mathbf{C}, \mathbf{\varepsilon}) = (\gamma^x + \gamma^x \mathbf{C} + 2 \gamma^x \mathbf{C}^2) \mathbf{\varepsilon}, \]

where the \( \gamma^x \) are vector-valued functions of the six invariants

\[ I_1, I_2, I_3, \mathbf{\varepsilon} \cdot \mathbf{\varepsilon}, \mathbf{\varepsilon} \cdot \mathbf{\gamma}, \mathbf{\varepsilon} \cdot \mathbf{\varepsilon} \cdot \mathbf{\gamma} \cdot \mathbf{\varepsilon} \]

\[ \text{Theorem 2.10.12.} \]
and the temperature. We will defer the proof of this representation theorem to the end of the present section.

By Theorem 7.4.1, the reduced constitutive equation for the heat flux becomes

\[ q = E_n \left( 0 \delta^x \mathbf{1} + \delta^x \Delta_n + 2 \delta^x C_n^2 \right) \mathbf{D} \Theta_n, \]

Using the Hamilton-Cayley Theorem 1.14.12 to replace \( C_n^2 \) by \( \Delta_n \) and noting that

\[ \Delta \Theta_n = E_n^T q, \]

we have

\[ q = E_n \left( \Gamma \delta^x \mathbf{1} + \Gamma \delta^x \Delta_n + \Gamma \delta^x C_n^2 \right) E_n^T q. \]

Distributing the \( E_n \) and \( E_n^T \) factors as on p. 7.5.19 leads to

\[ q = \left( \Gamma \delta^x \mathbf{1} + \Gamma \delta^x \Delta_n + \Gamma \delta^x C_n^2 \right) q. \]

Now, the \( \Gamma \)'s are functions of the temperature and \( \mathbf{E}, \mathbf{E}^2, \mathbf{E}^3, \mathbf{D}, \mathbf{D}^2, \mathbf{D}^3, \mathbf{E} \cdot \mathbf{D}, \mathbf{E} \cdot \mathbf{D} \mathbf{D}, \mathbf{E} \cdot \mathbf{E} \cdot \mathbf{D}, \mathbf{E} \cdot \mathbf{D} \cdot \mathbf{D}, \mathbf{D} \cdot \mathbf{D}. \]

Hence, we already know that the invariants of \( \mathbf{E} \) and \( \mathbf{D} \) are equal, and it is left as Exercise 7.5.6 to show that

\[ \text{Exercise 7.1.1.} \]
\[ \mathbf{v} \cdot \mathbf{v} = g \cdot B_n g, \]
\[ \mathbf{v} \cdot \mathbf{C}_n = g \cdot B_n^2 g, \]
\[ \mathbf{v} \cdot \mathbf{C}_n^2 \mathbf{v} = I_3 g \cdot B_n^2 g - II g \cdot B_n g + III \mathbf{g} \cdot \mathbf{g}. \]

Thus, we have established

**Theorem 7.5.19.** If \( O \subset O^x (q) \), the reduced heat flux constitutive equation becomes

\[ q = (h_x^0 \mathbf{v} + h_x^1 B_n + h_x^2 B_n^2) g, \]

where the \( h_x^0 \)'s are scalar-valued functions of \( \theta \) and the invariants

\[ I_3, II, III, B_n, g \cdot g, q \cdot B_n g, q \cdot B_n^2 g. \]

Conversely, if the heat flux is given by the above constitutive equation, then the body is isotropic with heat flux response.

Of course, it follows immediately from the Hamilton-Legley theorem that the above constitutive equation can be written as

\[ q = (h_x^0 \mathbf{v} + h_x^1 \mathbf{v} + h_x^2 B_n) g, \]

where the \( h_x^0 \)'s are functions of \( \theta \) and the invariants

\[ I_3, II, III, B_n, g \cdot g, q \cdot B_n g, q \cdot B_n^2 g. \]
Exercise 7.5.7. Establish the converse assertion of Theorem 7.5.19 by direct computation.

Now let us suppose that the elastic body under consideration is fluid so that

\[ \mathbf{L}^x(T) = \mathbf{L}^x(\Psi) = \mathbf{L}^x(\gamma) = \mathbf{L}^x(\sigma) = \mathbf{U}. \]

According to Theorems 7.5.8 and 7.5.16, it is sufficient to require that

\[ \mathbf{L}^x(\Psi) = \mathbf{L}^x(\sigma) = \mathbf{U}. \]

Since \( \Omega \subset \mathbf{U} \), we can adapt with the representations that we have already established for isotropic bodies.

Exercise 7.5.8. Prove that

\[ \mathbf{L}^x(\Psi) = \mathbf{U} \text{ iff } \Psi = \Phi^x(\text{det} \mathbf{E}_1, \theta) \]

and

\[ \mathbf{L}^x(\sigma) = \mathbf{U} \text{ iff } \sigma = \Phi^x(\text{det} \mathbf{E}_1, q \cdot q, \theta) \cdot q. \]

(Hint: See the proofs of Theorems 4.2.3 and 7.5.11.)

It will be convenient to replace \( \text{det} \mathbf{E}_1 \) by \( \sqrt{\text{det} \mathbf{B}} \), and this leads us to

*See Theorem 7.5.12.*
\[ \psi = \psi^x (\eta, \theta) \]

\[ \tilde{T} = 2p \psi^x \frac{\partial \psi^x}{\partial \psi^x} \tilde{I} \]

\[ \eta = -\frac{\partial \psi^x}{\partial \theta} \]

\[ q = q^x (\eta, \theta) \]

Since \( \eta \) determines \( p \) through the differential density equation

\[ p = \frac{\rho_k}{\sqrt{\psi^x}} \]

we can write

\[ \psi = \psi^x (\rho, \theta) \]

and

\[ q = q^x (\rho, g, g, \theta) \]

\[ \text{Theorem 2.10.4.} \]
Then
\[ I = 2\rho^2 \left[ -\frac{e}{\rho} \frac{\partial \psi^x}{\partial \rho} \right] I \]

\[ = 2\rho \left( \frac{P_x}{\rho^3} \right) \frac{\partial \psi^x}{\partial \rho} \]

\[ = 2\rho P_x \left( -\frac{1}{2} \rho^2 i \right) \frac{\partial \psi^x}{\partial \rho} \]

\[ = -\rho^{-1} \left( \frac{P_x}{\rho} \right)^3 \frac{\partial \psi^x}{\partial \rho} I \]

\[ = -\rho^2 \frac{\partial \psi^x}{\partial \rho} I \]

Since \( \rho, \theta, \) and \( g \) are unaltered by a change of the reference configuration from \( x \) to \( \mu \), we have
\[ \psi^x = \psi^\mu = \psi^\mu, \quad \varphi^x = \varphi^\mu = \varphi^\mu. \]

We sum these results up as
\[ \text{Eq. p. 355}. \]
Theorem 7.5.20. A thermelastic body is a fluid iff

\[ \psi = \Phi^x(\rho, \theta), \]

\[ I = -\rho^2 \frac{\partial \Phi^x}{\partial \rho}, \]

\[ \eta = -\frac{\partial \Phi^x}{\partial \theta}, \]

\[ q = \Phi^x(\rho, \theta, g, g) g. \]

In the purely mechanical context, we found an elastic fluid to be Euler's compressible perfect fluid. However, in a thermomechanical setting a thermelastic fluid is evidently more general than a perfect gas. It will be instructive to extract the constitutive equations.
For a perfect gas, from Theorem 7.5.20,

For a perfect gas, one has the "equation of state" \( p v = RT \). Here, \( p \) is the pressure given by \( T = -p \frac{v}{\rho} \); \( v \) is the specific volume \( v = \frac{1}{\rho} \); \( T \) is the absolute temperature \( T = \Theta \); and \( R \) is a positive constant known as the gas constant. Thus, in our notation, the equation of state comes out as

\[ p = R \rho \Theta. \]

But, according to Theorem 7.5.20, \( p = \rho^2 \frac{\partial \Theta}{\partial \rho} (\rho, \Theta) \).

Thus, we have the differential equation

\[ \frac{\partial \psi}{\partial \rho} (\rho, \Theta) = R \rho^{-1} \Theta, \]

which may be integrated to yield

\[ \psi (\rho, \Theta) = R \Theta \ln \rho + f(\Theta). \]
Turning to the entropy relation, we have

$$\eta = -\frac{\partial S}{\partial p} (p, \theta) = -R \ln p + f'(\theta).$$

We can get a handle on $f'(\theta)$ through the specific heat,

$$c_v = \frac{\partial f}{\partial \theta}.$$

Here we have added the subscript $v$ to $c_v$ to agree with common usage. On substituting for $\eta$, we get

$$-\theta f''(\theta) = c_v.$$

For a perfect gas, $c_v$ is assumed to be a constant.

When,

$$f'(\theta) = -c_v \ln \theta + \text{const},$$

and

$$\eta = -R \ln p + c_v \ln \theta + \text{const}.$$

Finally, in gas dynamics the constitutive

'See Definition 7.3.1 and Theorem 7.3.2.'
equation for the heat flux \( q = \frac{d}{dt} (r, \theta, z, g \cdot q) \) is specialized to

\[ q = k(\theta) q \]

with the additional special cases

\[ k(\theta) = K = \text{const.} \]

and

\[ k(\theta) = 0 \]

being rather common. In the last special case above, we would refer to the gas as being a non-conductor.

At this point, we have a sufficiently complete constitutive theory for perfect gases to quit. However, with just a little more effort we can obtain a number of interesting and familiar relations whose
derivations are sometimes obtained in the traditional treatments.

From \( E = \psi + \theta \eta \) and our constitutive equations for \( \psi \) and \( \eta \) given on pages 7.5.28 and 7.5.29 we get

\[
E = f(\theta) - \theta f'(\theta).
\]

Thus, for a perfect gas the specific internal energy depends only on the absolute temperature.

The specific enthalpy is defined by

\[
h = E + pV,
\]

When the enthalpy is given by a constitutive equation of the form \( h = \tilde{h}(p, \theta) \), the specific

Definition 6.3.1.
Heat at constant pressure is defined by

\[ \bar{C}_p = \bar{C}_p(p, \Theta) = \frac{\partial \bar{t}}{\partial \Theta}. \]

For a perfect gas, \( pv = R \Theta \) and \( \bar{e} = \bar{e}(\Theta) \)

and therefore

\[ \bar{h} = \bar{e}(\Theta) + R \Theta \]

and

\[ \bar{C}_p = \frac{\partial \bar{e}}{\partial \Theta}(\Theta) + R = \bar{c}_v + R, \]

where we have used Theorem 7.3.2. Consequently, for a perfect gas, the enthalpy depends only on the absolute temperature and

\[ R = \bar{C}_p - \bar{c}_v, \]

that the gas constant is the difference in the specific heats allows us to rewrite the constitutive equation

\[ m = -R \ln p + C \Theta + \text{const}. \]
First we make the replacement $j = \frac{1}{\nu}$ to get

$$\gamma = -R \ln \nu^{-1} + \gamma_0 \ln \Theta + \text{const.}$$

$$= R \ln \nu + \gamma_0 \ln \Theta + \text{const.}$$

$$= \ln v^R + \ln \Theta^{\gamma_0} + \text{const.}$$

$$= \ln (v^R \Theta^{\gamma_0}) + \text{const.}$$

Since $\Theta = \frac{p_0}{R}$, we can write

$$\gamma = \ln \left[ v^R \left( \frac{p_0}{R} \right)^{\gamma_0} \right] + \text{const.}$$

$$= \ln \left[ (v^{R+\gamma_0}) (p_0^{\gamma_0}) (R^{-\gamma_0}) \right] + \text{const.}$$

$$= \ln \left[ (v^{R+\gamma_0}) (p_0^{\gamma_0}) \right] + \ln R^{-\gamma_0} + \text{const.}$$

$$= \ln \left[ (v^{R+\gamma_0}) (p_0^{\gamma_0}) \right] + \text{const.}$$

Here, of course, the value of the additive const has changed.

We can get additional simplifications by recognizing that $R + \gamma_0 = c_0$. and introducing the customary notation...
Then
\[ y = \ln \left[ \frac{v^3 p}{c_v} \right] + \text{const.} \]
\[ = \ln \left[ \frac{v c_v p}{c_v} \right] + \text{const.} \]
\[ = c_v \ln (p v^3) + \text{const.} \]

This is the usual textbook formula for the entropy of a perfect gas.

We now return to the representation theorem needed on p. 7.5.21 for an isotropic vector-valued function of a symmetric tensor and a vector.

**Exercise 7.5.9.** Define \( S(V_n) = \{ S | S \in \mathcal{T}(V_n), S = S^T \} \).

Show that \( S(V_n) \) is a subspace of \( \mathcal{T}(V_n) \).

**Theorem 7.5.21.** Let \( \phi : S(V_3) \times V_3 \to V_3 \) be isotropic, i.e.,
\[ x(QAQ^T, Qy) = Qx(A, y) \quad \forall Q \in O, \]

then \( x \) admits the representation
\[ x(A, y) = (y_0 \mathbb{1} + y_1 A + y_2 A^2) y, \]

where the \( y_i \)'s are functions of the joint invariants
\[ I_A, II_A, III_A, y \cdot y, y \cdot A y, y \cdot A^2 y. \]

Conversely, a function \( x \) of this form is isotropic.

Proof. The proof of the converse assertion is straightforward and constitutes Exercise 7.5.10.

To establish the main assertion, we suppose that \( x \) is an isotropic function and write
\[ b = x(A, y), \]

Next let \( \{ \xi^i \} \) be an eigenvector basis for \( A \)
and denote the components of \( b, y, \) and \( A \) relative to this
basis by $\tilde{u}^{(i)}$, $\tilde{u}^{(j)}$, and $\text{diag} (a_1, a_2, a_3)$.

Consider the equations:

$$
\begin{align*}
\tilde{b}^{(1)} &= (\gamma_0 + \gamma_1 a_1 + \gamma_2 a_1^2) \tilde{u}^{(1)} \\
\tilde{b}^{(2)} &= (\gamma_0 + \gamma_1 a_2 + \gamma_2 a_2^2) \tilde{u}^{(2)} \\
\tilde{b}^{(3)} &= (\gamma_0 + \gamma_1 a_3 + \gamma_2 a_3^2) \tilde{u}^{(3)}
\end{align*}
$$

If each $\tilde{u}^{(i)} \neq 0$, then we can divide by the $\tilde{u}^{(i)}$s and view (*) as a set of linear algebraic equations for the $\tilde{b}^{(i)}$. The determinant of the coefficient matrix is

$$
\begin{vmatrix}
1 & a_1 & a_1^2 \\
1 & a_2 & a_2^2 \\
1 & a_3 & a_3^2
\end{vmatrix} = (a_1 - a_2)(a_2 - a_3)(a_3 - a_1).
$$

Thus, if we also assume that the eigenvalues of $A$ are distinct, then the $\tilde{b}^{(i)}$s are well-defined by (*)

In order to interpret (*), we use the spectral...
resolutions

\[ Z = \sum_{i=1}^{3} \epsilon_i \otimes \epsilon_i \]

\[ A = \sum_{i=1}^{3} a_i \epsilon_i \otimes \epsilon_i \]

\[ A^2 = \sum_{i=1}^{3} a_i^2 \epsilon_i \otimes \epsilon_i \]

to write

\[ \delta_0 Z + \delta_1 A + \delta_2 A^2 = \sum_{i=1}^{3} \left( \nu_i + \delta a_i + \delta a_i^2 \right) \epsilon_i \otimes \epsilon_i \]

Then since

\[ \nu = \langle \xi | y \rangle \epsilon_j \]

and

\[ (\epsilon_i \otimes \epsilon_j) \epsilon_i \otimes \epsilon_j = \delta_{ij} \epsilon_i \otimes \epsilon_i \] (no sum),

\[ (\delta_0 Z + \delta_1 A + \delta_2 A^2) \nu = \sum_{i=1}^{3} \left( \nu + \delta a_i + \delta a_i^2 \right) \xi \otimes \epsilon_i \]

Therefore,

\[ \left[ (\delta_0 Z + \delta_1 A + \delta_2 A^2) \nu \right] \cdot \epsilon_i \otimes \epsilon_i = \left( \nu + \delta a_i + \delta a_i^2 \right) \epsilon_i \otimes \epsilon_i \] (no sum).

Thus, (*) implies

\[ \delta = (\delta_0 Z + \delta_1 A + \delta_2 A^2) \nu \]
and since $z = v(A, u)$ by definition, we are close to the desired representation.

Clearly the $x_0$ as defined by (x) will depend on $A$ and $u$, and we write $x_0 = x_0(A, u')$. In order to investigate this dependence, we put

$$A' = QAQ^T, \quad u' = Qu, \quad z' = v(A', u')$$

where $Q$ is an arbitrary orthogonal tensor. By the isotropy,

$$z' = Qz.$$

We can now proceed just as before through an eigenvector basis for $A'$ to the representation

$$z' = (x_0'z + x_1'A'z + x_2'A'^2z)u'$$

where the $x_i$'s are determined by...
\[ b^i \langle i \rangle = (\gamma_0 + \gamma_1 a^i_1 + \gamma_2 a^i_1^2) w^i \langle i \rangle \]

\[ b^2 \langle 2 \rangle = (\gamma_0 + \gamma_1 a^2_2 + \gamma_2 a^2_2^2) w^2 \langle 2 \rangle \quad \text{(*)} \]

\[ b^3 \langle 3 \rangle = (\gamma_0 + \gamma_1 a^3_3 + \gamma_2 a^3_3^2) w^3 \langle 3 \rangle \]

Now suppose that \((a^i_0, e_i)\) is an eigenpair for \(A\) and consider

\[ A^\prime (Q e) \]

\[ = (QAQ^T)(Q e) = QA e = a(Q e). \]

Thus, \((a, Q e)\) is an eigenpair of \(A^\prime\). In particular,

\[ a^i_0 = a^i_0 \quad (i = 1, 2, 3) \]

and \(\{Q e_i\}\) is an eigenvector basis for \(A^\prime\). Taking \(\{Q e_i\}\) to be the eigenvector basis for \(A^\prime\) used in \(\text{(*)}\), we have

\[ \text{Here we have an alternative approach to Exercise 92.} \]
\[ b^i <i> = b^i \cdot Q^* <i> = \mathbf{e}^*_{<i>} \cdot Q^T b^i \]
\[ = \mathbf{e}^*_{<i>} \cdot Q^T \mathbf{Q} b = \mathbf{e}^*_{<i>} \cdot b = b_{<i>}. \]

Similarly,
\[ a^i <i> = a^i \cdot Q^* <i> = \mathbf{u}^*_{<i>}. \]

Thus, the \( b^i \)'s are determined by the same equations as the \( a^i \)'s, e.g.,
\[ \delta_0 (QAG^T, Qg) = \delta_0 (A, u) + Q g \in \Omega. \]

That is \( \delta_0 \) is an isotropic scalar-valued function of a symmetric tensor and a vector. Consequently, by a representation theorem whose proof we defer, \( \delta_0 \) depends on \( A \) and \( u \) only through the joint invariants \( \Gamma_A, \Pi_A, \pi_A, u \cdot v, u \cdot A u, u \cdot A^2 u. \)

\[ '\text{Theorem 7.5.22.} \]
This completes the proof of Theorem 7.5.21 in the case where none of the components of $\mathbf{y}$ relative to $E^\mathbf{e}_{23}^*$ vanish and where the eigenvalues of $A$ are distinct. We now turn to the removal of these restrictions.

Consider the isotropy condition

$$x(QAQ^T, Qy) = Qx(A, y) \quad \forall Q \in \mathcal{O}$$

and choose $Q$ to be a reflection in the $E_{23}^*$ plane.

Then $Qe_{23}^* = -e_{23}^*$, $Qe_{12}^* = e_{12}^*$, $Qe_{21}^* = e_{21}^*$,

and $Qy = Q(y + e_{23}^*) = -y + e_{21}^* + e_{12}^* + e_{23}^* + e_{23}^*$.

with a similar result holding for $Qe_{23}^*$. But by Exercise 4.2.2, $QAQ^T = A$. Consequently, for this choice of $Q$ the isotropy condition implies

$^1$ See p. 4.2.3.
\[ \chi \left( A_1, -\sum_{i} \chi^{(i)} e^{(i)} + \sum_{i} \eta^{(i)} \epsilon^{(i)} + \sum_{i} \xi^{(i)} \zeta^{(i)} \right) = -b^{(1)} e^{(1)} + b^{(2)} e^{(2)} + b^{(3)} e^{(3)} \]

But also
\[ \chi \left( A_1, \sum_{i} \pi^{(i)} e^{(i)} + \sum_{i} \eta^{(i)} \epsilon^{(i)} + \sum_{i} \xi^{(i)} \zeta^{(i)} \right) = \sum_{i} b^{(i)} e^{(i)} + \sum_{i} b^{(i)} \epsilon^{(i)} + \sum_{i} b^{(i)} \zeta^{(i)} \]

From these two equations, we see that
\[ \mathbf{b}^{(1)} = 0 \Rightarrow \mathbf{b}^{(1)} = -\mathbf{b}^{(1)} \Rightarrow \mathbf{b}^{(1)} = 0. \]

By other obvious choices for \( \mathbf{b} \), we get similar results for the second and third components. Thus,

for each \( i \), \( \mathbf{b}^{(i)} = 0 \Rightarrow \mathbf{b}^{(i)} = 0. \)

Therefore, if \( \mathbf{b}^{(i)} = 0 \) for some \( i \), the corresponding equation of (x)
\[ \mathbf{b}^{(i)} = (\lambda_0 + \lambda_1 a_i + \lambda_2 a_i^2) \mathbf{b}^{(i)} \]

is trivially satisfied independent of \( \lambda_0 + \lambda_1 a_i + \lambda_2 a_i^2 \).

In such a case, we set
\[ x + x a_i + x a_i^2 = 0 \]
in order to complete our set of equations for the $x_i$'s. This scheme works if more than one of the $x_i$'s vanish, of course, if they all vanish, then $y=0$ and the representation holds trivially since $V(A,0) = 0$.

Exercise 7.5.10. We can read off that $V(A,0) = 0$ from the result on the previous page that $\xi < v \Rightarrow \xi < v = 0$.

Show that $V(A,0) = 0$ more directly by making the choice $a_3 = -1$ in the isotropy condition.

Treating the next theorem, we complete the present proof by leaving the case of repeated eigenvalues of $A$ as Exercise 7.5.12.

if $a_2 = a_3$, pick $\xi < v = \frac{y - (y, x_1 x_1 e_1) x_1}{|y - (y, x_1 x_1 e_1) x_1|}$

to get $\xi < v = 0 \Rightarrow b_2 = 0$ taking care of $2^{nd}$.$
Theorem 7.5.22. Let \( \varphi : S(\frac{3}{2}) \times \frac{3}{2} \rightarrow \mathbb{R} \) be isotropic, i.e.,

\[
\varphi(QA Q^T, Qv) = \varphi(A, v) \quad \forall Q \in O,
\]

then \( \varphi \) admits the representation

\[
\varphi(A, v) = \varphi(I_A, I_A, \overline{\gamma} A, v, u, u \cdot Au, u \cdot A v^2).
\]

Conversely, a function \( \varphi \) of this form is isotropic.

Proof. The proof of the converse assertion presents no difficulties.

Let \( \{ e_i \} \) be an arbitrary but fixed orthonormal basis for \( V_5 \) and write

\[
\varphi(A, v) = \varphi(A^{\cdot i}, u^{\cdot i}),
\]

where \( A^{\cdot i} \) and \( u^{\cdot i} \) are the components of \( A \) and \( u \).
relative to $\mathbb{E}^{<i>3}$. Then the isotropy condition becomes

$$\langle (QAQ^T)^{<i>}, (Qu)^{<i>} \rangle = \langle A^{<i>}, u^{<i>} \rangle.$$  (*)

Choose $Q$ to be the orthogonal tensor which maps

the eigenvector basis $\mathbb{E}^{<i>3}$ for $A$ into $\mathbb{E}^{<i>3}$, i.e.,

$$Q^{*}e^{<i>} = e^{<i>}.$$ By Exercise 4.2.6,

$$[Q(AQ)^{<i>}] = \text{diag} (a_1, a_2, a_3);$$

also

$$\langle Qu^{<i>} \rangle = e^{<i>} \cdot Qu = u^{<i>} \cdot Q^T e^{<i>} = u^{<i>} e^{<i>} = u^{<i>};$$

Hence,

$$\langle A^{<i>}, u^{<i>} \rangle = \langle \delta_j a_j, u^{<i>} \rangle.$$ (**)  

Now return to (*) and choose $Q$ to be a reflection in the $e^{<2>}, e^{<3>}$ plane. Then following the argument

'See Theorem 1.13.4.'
On pp. 7.5.41-42, we see that
\[ \gamma(A^{<i>}, u^{<i>}, u^{<j>}, u^{<k>}) = \gamma(A^{<i>}, u^{<j>}, u^{<k>}, u^{<i>}) \].

In general, \( \gamma \) is even in each of the components of \( u \) (relative to an orthonormal basis), and consequently
\[ \gamma(A^{<i>}, u^{<i>}) = \gamma(A^{<i>}, (u^{<i>}^2). \]

---

**Exercise 7.5.13.** Prove the following theorem: Let \( f \) be

a real-valued function on the reals \( \Rightarrow f(x) = f(x), \) i.e.

let \( f \) be even. Then \( \exists \) another function \( g \) (on the

reals into the reals) \( \Rightarrow f(x) = g(x^2). \)

---

In particular, we can write \((***)\) as
\[ \gamma(A, u) = \Gamma(a_i, (u^{<i>}^2). \]

(***)

Next consider
\[ \mu \cdot A \mu = \mu \cdot [a_1 \hat{e}_{i_1} \otimes \hat{e}_{i_1} + \cdots ] \mu \]
\[
= y \cdot \left[ a_1 \cdot (\mathbf{e}_{<17} \cdot y) \right] + \ldots
\]

\[
= a_1 \left( \mathbf{e}_{<17} \cdot y \right)^2 + \ldots
\]

\[
= a_1 (\mathbf{e}_{<17})^2 + a_2 (\mathbf{e}_{<20})^2 + a_3 (\mathbf{e}_{<3})^2
\]

With similar considerations for \( y \cdot A^2 y \) and \( y \cdot y \),

we have the identities

\[
(\mathbf{e}_{<17})^2 + (\mathbf{e}_{<20})^2 + (\mathbf{e}_{<3})^2 = y \cdot y
\]

\[
a_1 (\mathbf{e}_{<17})^2 + a_2 (\mathbf{e}_{<20})^2 + a_3 (\mathbf{e}_{<3})^2 = y \cdot A y
\]  

(\#)

\[
a_1^2 (\mathbf{e}_{<17})^2 + a_2^2 (\mathbf{e}_{<20})^2 + a_3^2 (\mathbf{e}_{<3})^2 = y \cdot A^2 y
\]

Viewing (\#) as a set of linear equations for the \( a_i^2 \),

the determinant of the coefficient matrix is

\[
\begin{vmatrix}
1 & 1 & 1 \\
a_1 & a_2 & a_3 \\
a_1^2 & a_2^2 & a_3^2
\end{vmatrix} = (a_1-a_2)(a_2-a_3)(a_3-a_1).
\]

Assuming that the eigenvalues of \( A \) are distinct, we see
from (4) that the $(i<1>)^2$ are determined by the $a_i$ and $u_1$, $u_2$, $u_3$, $u_4$. But, of course, the $a_i$ are determined by the fundamental invariants $I_A$, $I_B$, $I_C$.

Combining the above result with (***), we have the desired representation

$$\psi(A, u) = Q(I_A, I_B, I_C, u_1, u_2, u_3, u_4)$$

The removal of the restriction of distinct eigenvalues is left as Exercise 7.5.14. □

Shorter but less transparent proofs of Theorems 7.5.21 and 7.5.22 have been provided by Noll and

Wang. The proofs given here are patterned after Senin's proof of Theorem 4.2.1.

7.6. Internal Constraints.

Since biomechanical constraints have been investigated only relatively recently and since the several investigations have taken different starting points and have reached different end points, some comments on the references given at the end of the section are in order. We are following the 1970 paper by Shen, Nagdhi, and Trapp with some minor differences in technique and assumptions. The 1973 paper by Andressi and Guidugli takes a starting point close to Nolla's theory of mechanical constraints (our §3.6), but this

\[\text{The 1971 paper by Trapp uses this theory to model materials reinforced with inextensible cords.}\]
writer finds the analysis unsatisfactory and is unable to correct it without changing the starting point. The 1973 paper by Antar and Twidale is difficult to relate to because of its abstractness; it probably gives the shear, Nagahi, Trapp theory a more general setting (especially the second alternative).

Definition 7.6.1. A body $B$ is said to be thermomechanically constrained at the particle $x$ with respect to the reference configuration $\varphi$ iff $\exists$ functions $A^x : T(V) \times R^+ \rightarrow S(V)$, $b^x : T(V) \times R^+ \rightarrow R$, $\xi^x : T(V) \times R^+ \rightarrow T$ such that $\varphi$ is the rate of

\[ \text{Not necessarily thermoelectric.} \]
The material time derivative of the deformation tensor \( \mathbf{D} \), the temperature \( \Theta \), and the spatial temperature gradient \( \mathbf{g} \) are required to satisfy

\[
A^x_n \left( \mathbf{F}(\mathbf{x}, t), \Theta(\mathbf{x}, t) \right) \cdot \mathbf{D}_n(\mathbf{x}, t) + b^x_n \left( \mathbf{F}(\mathbf{x}, t), \Theta(\mathbf{x}, t) \right) \dot{\Theta}_n(\mathbf{x}, t) + c^x_n \left( \mathbf{F}(\mathbf{x}, t), \Theta(\mathbf{x}, t) \right) \cdot \mathbf{g}_n(\mathbf{x}, t) = 0 \quad \forall \, t. 
\]

In the above definition we are using the notations:

\[
A^x_n \cdot \mathbf{D}_n = \text{tr} \left( A^x_n \mathbf{D}_n^T \right); \\
\mathcal{T}(\mathbf{Y}_n) = \{ \mathbf{I} \in \mathcal{T}(\mathbf{Y}_n) \text{ and } \det \mathbf{I} > 0 \}; \\
R = \{ n \mid n \text{ real} \}; \\
R^+ = \{ n \mid n \in R \text{ and } n > 0 \}. 
\]

\(^1\) Definition 2.4.7.

\(^2\) See, e.g., Theorem 6.3.1

\(^3\) Definition 7.1.1.

\(^4\) Theorem 11.3.

\(^5\)
\[ x = x_0(x). \]

Generally, we shall write \((\text{TMC})\) in the almacen form

\[ A \cdot \Delta + b \partial + \rho \cdot g = 0, \]

The constraint of incompressibility is stated through \((\text{TMC})\) by taking \( A = 1, b = 0, \rho = 0 \) to get

\[ 1 \cdot \Delta = 0 \quad \text{or} \quad \Delta = 0 \]

and then noting Exercise 2.4.2 and Theorem 2.6.6.

Theorem 7.6.1. If a body \( B \) is thermomechanically constrained w.r.t. one reference configuration, then it is thermomechanically constrained w.r.t. any other reference configuration.

Proof. Suppose that \( B \) is thermomechanically constrained w.r.t. \( x_0 \) so that
\[ A^x_n (F_n (x,t), \Omega_n (x,t)) \cdot D_n (x,t) + b \tilde{\Omega} + \phi \cdot g = 0. \]

(We shall just work on the first term; the others are handled in an identical manner.) Let \( \mu \) be an other reference configuration. It is connected to \( \xi \) through the deformation \( f = \mu \circ \xi^{-1} \). By Theorem 2.0.2, \[ F_n (x,t) = \frac{F_\mu (Y,t)}{\mu (X)} \cdot \nabla f (X) \]
where \( Y = \mu (X) \). Also, \[ \theta_n (x,t) = \tilde{\Omega} (x,t) = \tilde{\Omega} (\mu^{-1} (Y,t)) = \theta_\mu (Y,t) , \]
and in the same way \( D_n (x,t) = D_\mu (Y,t) \). Thus, \[ A^x_n (F_n (x,t), \theta_n (x,t)) \cdot D_n (x,t) \]
\[ = A^x_n (F_\mu (Y,t) \cdot \nabla f (X), \theta_\mu (Y,t)) \cdot D_\mu (Y,t) \]

\[ ^1 \text{Definition 2.1.2, } (B_\mu). \]
\[ = A^x_{\mu} (F_{\mu}(x, t), \Theta_{\mu}(x, t)) \cdot D_{\mu}(x, t) \]

where

\[ A^x_{\mu}(\cdot, \cdots) = A^x_{\mu}(\cdot) \nabla f(x), \cdots \]

Consequently,

\[ A^x_{\mu}(F_{\mu}(x, t), \Theta_{\mu}(x, t)) \cdot D_{\mu}(x, t) + b^x_{\mu}(F_{\mu}(x, t), \Theta_{\mu}(x, t)) \cdot g_{\mu}(x, t) \]

\[ + c^x_{\mu}(F_{\mu}(x, t), \Theta_{\mu}(x, t)) \cdot g_{\mu}(x, t) = 0, \]

i.e., \( B \) is thermomechanically consistent at \( x \) w.r.t. the reference configuration \( \mu \).

Since the coefficients in (TMC) are given by constitutive equations, we expect them to be objective; thus, we require that

The coefficients in (TMC) must satisfy the principle of material indifference, i.e.,
\[ A^x(QF, \theta) = QA^x(F, \theta)Q^T, \]
\[ b^x(QF, \theta) = b^x(F, \theta), \]
\[ p^x(QF, \theta) = Qp^x(F, \theta) \]
\[ \forall Q \in \Theta(V_3), F \in \mathcal{T}^+(V_3), \theta \in \mathbb{R}^+ \]

Fortunately, such invariance requirements have already been investigated in Theorems 3.2.2, 3.6.2, and 7.4.1.

We have then

**Theorem 7.6.2.** If the coefficients in (TMC) satisfy the principle of material indifference, they can be written in the desired form:

\[ A = A^x(F, \theta) = F \bar{A}^x(C, \theta)F^T, \]
\[ b = b^x(F, \theta) = \bar{b}^x(C, \theta), \]
\[ \zeta = \zeta^x(F, \theta) = F \bar{\zeta}^x(C, \theta) \]
Conversely, the above reduced constitutive equations satisfy the principle of material indifference.

Since $D$, $\Theta$, and $\varphi$ are objective, i.e.,

$$
\hat{D} = QDQ^T, \quad \hat{\Theta} = \Theta, \quad \hat{\varphi} = Q\varphi; 
$$

it is not surprising that (TMC) itself meets the principle of material indifference (when the coefficients are in reduced form) in the sense that

$$
\begin{align*}
\left[ \tilde{F}_N A^x (C_m, \Theta) \tilde{F}^T_m \right] \cdot \hat{D} + \tilde{B}_N^x (C_m, \Theta) \hat{\Theta} + \left[ \tilde{F}_N C^x (C_m, \Theta) \right] \cdot \hat{\varphi} \\
= \left[ \tilde{F}_N A^x (C_m, \Theta) \tilde{F}^T_m \right] \cdot \hat{D} + \tilde{B}_N^x (C_m, \Theta) \hat{\Theta} + \left[ \tilde{F}_N C^x (C_m, \Theta) \right] \cdot \hat{\varphi} = \hat{\gamma}
\end{align*}
$$

We leave the details as Exercise 7.6.1.

---

*See Exercise 5.1.4, p. 7.4.1, and p. 7.4.3, respectively.

*Here, as usual, a superscript * indicates an equivalent motion. See Definition 3.2.1.
In order to proceed, we make the following assumption.

**Principle of Determinism for Thermomechanically Constrained Materials.** The histories \( \varepsilon^{(e)}_m, \theta^{(e)}_m, f^{(e)}_m \) determine the stress \( \sigma \), the free energy \( \psi \), the entropy \( \eta \), and the heat flux \( q \) only to within additive reactions \( T_R, \psi_R, \eta_R, \) and \( q_R \) that do not contribute to entropy production in any process satisfying the constraint, i.e.,

\[
\begin{align*}
\sigma &= \sigma_R + \sigma_E \\
\psi &= \psi_R + \psi_E \\
\eta &= \eta_R + \eta_E \\
q &= q_R + q_E
\end{align*}
\]

(TMCM)

See Theorem 6.3.3.

*In the case of \( \tau = 1 \) and \( \tau \rightarrow \infty \).
\[ \mathbf{J} \cdot \mathbf{D} - p \mathbf{J} \mathbf{R} \mathbf{Q} + \frac{1}{2} \mathbf{J} \mathbf{R} \mathbf{Q} + \mathbf{Q} R = 0 \]

\forall \mathbf{D}, \mathbf{Q}, \mathbf{Q} \text{ that satisfy the thermomechanical constraint} \quad \mathbf{A} \cdot \mathbf{D} + \mathbf{b} \mathbf{Q} + \mathbf{c} \cdot \mathbf{Q} = 0.

The extra stress, extra free energy, extra entropy, and extra heat flux \((f_E, u_E, \theta_E, \text{ and } q_E, \text{ respectively})\) are given by constitutive equations in the usual way.

It is important to realize that the constitutive equations for \(f_E\) etc. may be very general. That is, at this point, our theory of thermomechanical constraint is not restricted to thermoelasticity. On the other hand, the constraint (TMC) might be much more general.

The condition of null entropy production and the
constraint itself are most easily investigated if we introduce the set \( S(V_3) \times \mathbb{R} \times V_3 \). The typical element of this set is an ordered triple whose elements (in order) are a second-order tensor, a real, and a vector.

Exercise 7.6.2. Show that with the obvious definitions for addition, etc., \( S(V_3) \times \mathbb{R} \times V_3 \) is a vector space.

Exercise 7.6.3. Show that

\[
(I_1, r_1, v_1) \cdot (I_2, r_2, v_2) = I_1 \cdot I_2 + r_1 r_2 + v_1 \cdot v_2
\]

defines an inner product on \( S(V_3) \times \mathbb{R} \times V_3 \).

With the above scheme in mind we write

\[
\Sigma = (I_R, -g_R, \frac{1}{2} g_R),
\]

\[
\Lambda = (A^t, b, \alpha),
\]
\( \Phi = (2, \delta, q) \).

Then our principle of determinism states that
\[ \sum - \Phi + \rho R = 0 \quad \forall \Phi \in \Delta \cdot \Phi = 0. \]

Choosing \( \Phi = (0,0,0) \), we get
\[ \dot{\Psi} = 0 \Rightarrow \Psi \text{ constant in } t. \]

Thus, we are left with
\[ \sum \cdot \Phi = 0 \quad \forall \Phi \in \Delta \cdot \Phi = 0. \]

Then by the supplement to \( \xi 1.14 \),
\[ \sum = \alpha \Delta \]

for some \( \alpha \in \mathbb{R} \). We sum these results up as

**Theorem 7.6.3.** The reactions in a body subject to the thermomechanical constraint

\[ A \cdot \dot{D} + b \dot{\Theta} + c \cdot \dot{q} = 0. \]
are given by

\[ \tilde{F}_R(x, t) = \alpha(x, t) A_n^x (F^*(x, t), \Theta_n (x, t)) \]

\[ \tilde{F}_\nu(x, t) = -\frac{\alpha(x, t)}{\beta(x, t)} B_n^x (F^*(x, t), \Theta_n (x, t)) \]

\[ \tilde{\Theta}_R(x, t) = \alpha(x, t) \Theta_n (x, t) \Theta^x_n (F^*(x, t), \Theta_n (x, t)) \]

\[ \tilde{\Phi}_R(x, t) = \beta(x) \]

where the functions \( \alpha \) and \( \beta \) are arbitrary.

Of course, the response functions for \( A, B, \) and \( \beta \) in Theorem 7.6.3 are subject to the principle of material indifference. The functions \( \alpha \) and \( \beta \) are analogous to \( q \) in Theorem 3.6.3.

Since \( \Phi_R \) is constant (in time), it drops out of the energy equation and the Clausius-Donohue inequality.

\[ \text{See Theorem 7.6.2.} \]
It is reasonable then to agree to take

$$\psi_R = 0,$$

the theory by Green, Naghdi, and Trapp and by

Gurtin and Guidugli assume this at the start (of course,
in anticipation of the fact that if the assumption is not made, it still
comes out as a constant).

Next we consider the principle of material indifference

for thermomechanically constrained bodies. By (TMCM),

Theorem 7.6.2, and Theorem 7.6.3, the constitutive

equation for the stress, e.g., is

$$\sigma = \alpha \bar{F} \bar{A}^x (\bar{C}_m, \bar{\Theta}_m) \bar{F}^T + \bar{T}_E.$$

For the equivalent motion \( \{ \dot{x}^e (\cdot, t) \} \), we have

$$\ddot{x}^e = \alpha \dot{\bar{F}} \bar{A}^x (\bar{C}_m, \bar{\Theta}_m) \dot{\bar{F}}^T + \ddot{x}^e.$$
Since \( \mathbf{\dot{F}} = Q \mathbf{\dot{F}_n} \), \( \mathbf{\dot{C}}_n = \mathbf{\dot{C}_n} \), and \( \mathbf{\dot{\Theta}}_n = \mathbf{\dot{\Theta}_n} \),

\[
\mathbf{\dot{I}} = \alpha Q \mathbf{\dot{F}} \mathbf{\dot{A}}^x_n (\mathbf{\dot{C}_n}, \mathbf{\dot{\Theta}_n}) F_\mathbf{\dot{E}}^T \mathbf{Q}^T + \mathbf{\dot{J}}_E
\]

But material indifference requires that \( \mathbf{\dot{J}} = Q T Q^T \),

and therefore

\[
\alpha Q \mathbf{\dot{F}} \mathbf{\dot{A}}^x_n (\mathbf{\dot{C}_n}, \mathbf{\dot{\Theta}_n}) F_\mathbf{\dot{E}}^T \mathbf{Q}^T + \mathbf{\dot{J}}_E
\]

\[
= \alpha Q \mathbf{\dot{F}} \mathbf{\dot{A}}^x_n (\mathbf{\dot{C}_n}, \mathbf{\dot{\Theta}_n}) F_\mathbf{\dot{E}}^T \mathbf{Q}^T + Q T E Q^T
\]

or

\[
\mathbf{\dot{J}}_E = Q T E Q^T.
\]

A similar result holds for the other fields. Formally, we have

**Theorem 7.6.4.** Let \( A, b, \) and \( c \) be expressed in the reduced forms of Theorem 7.6.2. Then the constitutive equations (TMCM) satisfy the principle of material indifference iff the constitutive equations for \( T_E, Q_E \)
\( \gamma_E \) and \( \gamma_I \) satisfy material indifference.

The next result is an immediate consequence of the requirement that the reactions not contribute to the entropy production.

\[ \text{Theorem 7.6.5.} \] A necessary and sufficient condition that every admissible local thermochemical process corresponding to the constitutive equations (TMCM) satisfy the reduced local dissipation inequality is that every admissible local thermochemical process (consistent with the constraint (TMC)) and corresponding to the constitutive equations for \( \gamma_E \), \( \gamma_I \), \( \gamma_E \), and \( \gamma_I \) satisfy the reduced local dissipation inequality.

\[ \text{Cf. Theorem 7.2.2}. \]
Put more simply: The reactions drop out of the second law, and the Clausius-Duhem inequality need be applied only to the constitutive equations for the extra fields. Of course, for thermomechanically constrained materials, we must be careful not to violate the constraints in constructing special processes as in the lemma associated with Theorem 7.2.2.

Since the deformation gradient enters into the expressions for the reactions, the reactions must be considered in material symmetry considerations. Of course, in some special cases such as incompressibility, the dependence on the deformation gradient will drop out.

To be more specific, we consider the constitutive
equation for the stress

\[ J = x \tilde{A}(E, \theta) + I_E, \]

where we have used Theorem 7.6.3 to express the reaction stress \( J_R \). Suppose \( H \) is an element of the symmetry group of the material; then \( H \) must belong to the symmetry group for the stress response, which means that replacing \( E \) by \( EH \) in the constitutive equation for the stress does not change the stress. The

\[ x \tilde{A}(EH, \theta) + I_E |_{E=EH} = x \tilde{A}(E, \theta) + I_E. \quad (\star) \]

Now as far as the theory of constitutive equations is concerned, \( x \) is arbitrary. Hence, (\star) must hold for \( x \); an

\[ \text{See } \S \text{ 7.5.} \]
in particular, it must hold for \( x = 0 \). This yields

\[
\frac{\mathcal{E}}{\mathcal{E}_0} = \mathcal{E}_0, \\
\mathcal{E} = \mathcal{E}_0
\]

i.e., the extra stress by itself must meet the symmetry condition just as if the reaction stress were not present, \((**\)) and \((*) \Rightarrow \)

\[
\mathcal{A} \left( \mathcal{E}_0, \theta \right) = \mathcal{A} \left( \mathcal{E}, \theta \right)
\]

and so the reaction stress by itself must also satisfy the symmetry requirement.

Since the other constitutive equations can be handled in the same way, we have

**Theorem 7.6.6.** The reaction responses and the extra responses in \((\mathcal{TMCM})\) must individually satisfy any material symmetry requirements imposed on the body.
In view of the general nature of Theorem 7.6.6, we point out again that our deliberations are not yet restricted to thermoelastic materials. Of course, the restricted character of (TMC) is especially suited to thermoelasticity.

Now suppose that the material is isotropic (with &xi; an undistorted reference configuration) so that \( \partial < \partial \).

Let \( \partial < \partial \) then \( \partial^{T} < \partial \). By Theorems 7.6.6, 7.6.3, and 7.6.2

\[
\alpha \left[ \begin{array}{c}
\alpha \\
\beta
\end{array} \right] \bar{A}_{\partial}^{\partial} \left( \partial^{T} \partial, \theta \right) \partial^{T} = \alpha \bar{F} \bar{A}_{\partial}^{\partial} \left( \theta, \theta \right) \partial^{T},
\]

\[
-\frac{\alpha}{\beta} \bar{B}_{\partial}^{\partial} \left( \partial^{T} \partial, \theta \right) = -\frac{\alpha}{\beta} \bar{B}_{\partial}^{\partial} \left( \theta, \theta \right),
\]

\[
\alpha \theta \left[ \begin{array}{c}
\alpha \\
\beta
\end{array} \right] \bar{A}_{\partial}^{\partial} \left( \partial^{T} \partial, \theta \right) = \alpha \theta \bar{F} \bar{A}_{\partial}^{\partial} \left( \theta, \theta \right).
\]

With some rearranging, we get

\[
\bar{A}_{\partial}^{\partial} \left( \partial^{T} \partial, \theta \right) = \bar{Q} \bar{A}_{\partial}^{\partial} \left( \theta, \theta \right) \partial^{T},
\]
$\tilde{b}_n^x(QCQ^T, \theta) = \tilde{b}_n^x(\mathbf{c}, \theta)$,

$\overline{b}_n^x(QCQ^T, \theta) = Q \overline{b}_n^x(\mathbf{c}, \theta)$.

Since the equations must hold $\forall Q \in \Theta$ and $\forall$

$C \in S^+, \theta \in R^+$; $\tilde{A}_n^x$, $\tilde{b}_n^x$, and $\tilde{b}_n^x$ are isotropic

functions. By the proof of Theorem 4.2.1, $\tilde{A}_n^x$ and $\tilde{b}_n^x$

have the representations

$\tilde{A}_n^x(C_n, \theta) = \tilde{b}_n^x(I_C, \Pi_C, \Pi_C, \theta) \frac{1}{2} \bar{A}_n^x(-)C_n + \bar{A}_n^x(-)C_n^2$

and

$\tilde{b}_n^x(C_n, \theta) = \tilde{b}_n^x(I_C, \Pi_C, \Pi_C, \theta)$.

We have not considered the representation of an

isotropic vector-valued function of one symmetric tensor

before, but this is surprisingly easy. Choosing $Q = -1$

in $\overline{b}_n^x(QCQ^T, \theta) = Q \overline{b}_n^x(\mathbf{c}, \theta)$ yields

$\overline{A}_n^x(\mathbf{c}, \theta) = -\overline{A}_n^x(\mathbf{c}, \theta) \Rightarrow \overline{b}_n^x(\mathbf{c}, \theta) = 0$. 
Placing the expression for $\bar{A}^x$ back into Theorem 7.6.2 and following the proof of Theorem 4.2.2 leads to

$$A = a_n^x (I_B, I_B, III_B, \Theta) \frac{1}{T} + a_n^x (-)B_0 + a_n^x (-)B_2$$

As usual, the corresponding reactions are given by

Theorem 7.6.3. We sum these results up in

Theorem 7.6.7. Let a body subjected to the

thermochemical constraint

$$A_n^x (E_n, \theta) \cdot D + b_n^x (E_n, \theta) \cdot \phi + \lambda_n^x (E_n, \theta) \cdot g = 0$$

be isotropic at $x$ (with $E_n$ an undistorted reference configuration). Then

$$A_n^x (E_n, \theta) = a_n^x (I_B, I_B, III_B, \Theta) \frac{1}{T} + a_n^x (-)B_0 + a_n^x (-)B_2$$

$$b_n^x (E_n, \theta) = b_n^x (I_B, I_B, III_B, \Theta)$$

'Not necessarily thermoelastic.'
\[ \mathcal{F}^x_n(E_n, \theta) = 0 \];

and the reactions are given by

\[ I_R = \alpha \left[ a_n^x \left( I_{B_1}, I_{B_2}, I_{B_3}, \theta \right) + a_n^x \left( -I_{B_1} \right) B_n + a_n^x \left( -I_{B_2} \right) B_n^2 \right] \]

\[ \eta_R = -\frac{\alpha}{\rho} b_n^x \left( I_{B_1}, I_{B_2}, I_{B_3}, \theta \right), \]

\[ q_R = 0, \]

\[ \psi_R = 0. \]

The result that \( \mathcal{F} = 0 \) for isotropic materials can be interpreted as requiring the temperature gradient to be unconstrained.\(^2\) The Austin and Sturdivant theory leads to the conclusion that isotropy requires that either the temperature gradient is unconstrained

\[ ^1 \text{Recalling the agreement on p. 7.6.14.} \]

\[ ^2 \text{In our special class of thermochemical constraints} \]
on the material is a perfect conductor. The requirement of being a perfect conductor is a constraint on the temperature gradient, but we will find that the discrepancy noted here is not as severe as it may appear when we look at the constraint of perfect conduction.

Next suppose that the body is fluid. Since fluids are isotropic, we start with the representations of Theorem 7.6.7 and choose \( H = \left| \det F \right|^{\frac{1}{3}} E^{-1} \). Then as on p. 4.2.10, replacing \( E \) by \( E^2 \) leads to replacing
\[
B = \left| \det F \right|^{\frac{2}{3}} 1; \text{ whence,}
\]
\[
A = \hat{A}_x \left( \left| \det F_{n-1} \right|, \theta \right) \frac{1}{2}
\]
and
\[
b = \hat{b}_x \left( \left| \det F_{n-1} \right|, \theta \right).
\]

Cf. Theorems 4.2.3 and 7.5.11 and Exercise 7.5.8.
Formally, we have

**Theorem 7.6.8.** Let a body subjected to the thermomechanical constraint

\[ A^x(F_n, \theta) \cdot G + b^x(F_n, \theta) \cdot \dot{\theta} + c^x(F_n, \theta) \cdot \gamma = 0 \]

be fluid at \( x \). Then

\[ A^x(F_n, \theta) = \hat{A}^x \left( \det F_n, \theta \right) \frac{1}{2}, \]

\[ b^x(F_n, \theta) = \hat{b}^x \left( \det F_n, \theta \right), \]

\[ c^x(F_n, \theta) = 0; \]

and the reactions are given by

\[ \tau^x_R = \alpha \hat{a}^x \left( \det F_n, \theta \right) \frac{1}{2}, \]

\[ \gamma^x_R = -\frac{\alpha}{\rho} \hat{b}^x \left( \det F_n, \theta \right), \]

\[ \varphi^x_R = 0, \]

\[ \text{Not necessarily thermoelastic.} \]
\( \psi_R = 0 \).

Of course, we could easily use the density equation to replace \( \det \mathbf{E} \) by \( \rho \) in the above representations.

Justin and Andrew find that a fluid can at most be subjected to the constraint of temperature-dependent compressibility. What remains of \( (TM) \) for a fluid in our case appears to be slightly more general than temperature-dependent compressibility.

Recalling the agreement on p. 7.6.14.

\( ^2 \text{ Cf., p. 3.5.5 and p. 4.2.11, e.g.} \)

\( ^3 \text{ See Definition 7.6.2, Theorem 7.6.10, and Exercise 7.6.9.} \)
Next suppose that there are several constraints so that (TMC) is replaced by

$$\sum A \cdot \mathbf{P} + \sum b \mathbf{\dot{E}} + \sum e \cdot \dot{\mathbf{q}} = 0 \quad (i=1, 2, \ldots, m).$$

Of course, each of these constraint equations is subject to the principle of material indifference as on pp. 76.6 - 76.8. Each of the constraints will generate a set of reaction responses, and we replace (TMC) with

$$I = \sum_{i=1}^{m} I_R^i + I_E,$$

$$\psi = \sum_{i=1}^{m} \psi_R^i + \psi_E,$$

$$\gamma = \sum_{i=1}^{m} \gamma_R^i + \gamma_E,$$

$$\mathbf{q} = \sum_{i=1}^{m} \mathbf{q}_R^i + \mathbf{q}_E.$$

Each set of reactions should not contribute to the entropy production for any process consistent with the corresponding constraint, and hence we use Theorem 76.3 and the
agreement on p. 76.14 to write

\[ T = \sum \alpha_i A_i + T_E \]

\[ \gamma = -\sum \frac{\alpha_i}{P} b_i + \gamma_E \]

\[ q = \sum \alpha_i \theta_i \]

\[ \phi = \phi_E \]

as the constitutive equations for a material subjected to some thermomechanical constraints.

Finally, we consider some particular forms for (TMC).

**Incompressibility**

Here all motions are required to be isochoric, and as noted on p. 76.4 this corresponds to taking

\[ A = 1 \]

\[ b = 0 \]

\[ \varepsilon = 0 \] in (TMC). These choices
are consistent with the reduced forms of Theorem 7.6.2 if we take \( \tilde{D}^{x}(C_{w}, \Theta_{w}) = 0 \), \( \tilde{F}^{x}(C_{w}, \Theta_{w}) = 0 \), and \( \tilde{A}^{x}(C_{w}, \Theta_{w}) = C^{-1}_{w} = (E_{w}^{T}E_{w})^{-1} = E_{w}'(E_{w}')^{-1} \).

By Theorem 7.6.3 and the agreement on p. 7.6.14, the reactions for incompressibility are read off as stated below.

**Theorem 7.6.9.** For an incompressible material, the reactions are

\[
\tilde{\gamma}_{R}^{x}(x, t) = -\tilde{\rho}(x, t) \frac{1}{\tilde{E}_{w}},
\]

\[
\psi_{R} = \tilde{\gamma}_{R} = 0,
\]

\[
\tilde{\eta}_{R} = 0.
\]

We note that this result is consistent with Theorem 3.6.5.
Since the deformation gradient has dropped out of these reactions, they need not be considered in material symmetry considerations.

**Temperature-Dependent Compressibility**

As a natural generalization of the constraint of incompressibility, we have

**Definition 7.6.2.** A body \( \mathcal{B} \) is said to be subjected to a constraint of temperature-dependent compressibility at the particle \( x \) with respect to the reference configuration \( \mathcal{O} \) if there exists a function \( f^x : \mathbb{R}^+ \rightarrow \mathbb{R}^+ \) such that

\[
J^x_\infty (x, t) = f^x_\infty (\Theta^x (x, t)) + t. \quad \text{(TDC)}
\]

1. \(^{1}\) Cf. p. 4.2.11.

2. \(^{2}\) Cf. Definition 2.6.6.
To cast (TDC) into the form (TMC), we differentiate it w.r.t. t:

\[ \frac{\partial J_n(x,t)}{\partial t} = J_n(x,t) \frac{\partial}{\partial t} D_n(x,t), \]

\[ \frac{\partial}{\partial t} \left[ \frac{f_n^{x}}{\theta_n(x,t)} \right] = \left( \frac{f_n^{x}}{\theta_n(x,t)} \right)' \frac{\partial \theta_n(x,t)}{\partial t}, \]

Hence, we have

\[ \text{Theorem 7.6.10.} \quad (TDC) \implies \]

\[ f_n^{x} D_n(x,t) + \frac{\left( f_n^{x}' \theta_n(x,t) \right)}{f_n^{x} \theta_n(x,t)} \dot{\theta}_n(x,t) = 0 \quad \forall t \quad (TDC) \]

Exercise 7.6.4. Consider the converse of Theorem 7.6.10

We can put (DC) into the reduced form of

\[ \text{Theorem 7.6.2} \quad \text{by taking} \quad \bar{A}_n^{x}(c, \theta) = \frac{C_n}{\theta}, \quad \bar{B}_n^{x}(c, \theta) \]

\[ = -\frac{\left( f_n^{x}' \theta_n(x,t) \right)}{f_n^{x} \theta_n(x,t)} \Rightarrow \dot{\theta}_n = 0. \] Then by Theorem 7.6.3

See Theorem 2.6.5 and Exercise 2.4.2.
and the agreement on p. 76.14, we have

\begin{align*}
(\mathbf{r})_R(x, t) &= -\mathbf{P}_n(x, t) \mathbf{t}^\text{T}, \\
(\mathbf{r})_R(x, t) &= -\mathbf{P}_n(x, t) \left( f_n \right)^\text{T} \left( \mathbf{2}_n(x, t) \right), \\
\mathbf{x}_R &= 0, \quad \mathbf{y}_R = 0.
\end{align*}

We observe again that the deformation gradient has dropped out of the expressions for the reactions; and, thus for temperature-dependent incompressibility, the reactions drop out of material symmetry considerations.

\textbf{Perfect Conductor}

We can motivate the notion of a perfect

\textit{Here we have used the density equation (Theorem 2.10.4,}
conductor by considering the classical Fourier's law,

\[ q = k \frac{\partial T}{\partial x}. \]

For given \( q \), the higher the conductivity (i.e., the larger \( k \)), the smaller \(|q|\) must be. In the limit as \( k \to \infty \),

\[ q \to 0. \]

**Definition 7.6.3.** A body \( B \) is said to be a perfect conductor at the particle \( x \) if the spatial temperature gradient must vanish at \( x \), i.e.,

\[ \frac{\partial T}{\partial x} = 0, \quad \forall \tau \quad \text{(PC).} \]

Of course, usually a body would be required to be a perfect conductor at all its particles, and thus it could sustain only uniform temperature fields.

We can cast the constraint (PC) into three
constraints of the form (TMC) as follows. Let 

\[ \{ e_i \} \] be a basis for \( V_3 \), then \( \{ e_i' \} \) where 

\[ e_i' = F^T e_i \] is also a basis, \( F \) and (PC) is equivalent to \( g \cdot e_i = 0 \quad (i=1,2,3) \). \( (PC) \)

In terms of Theorem 7.6.2, we have 

\[ i_0 = F \cdot i_x (c_0, \theta_0) = e_i = (F^T)^{-1} e_i' \]

Thus, \( \iota_x \) \( (c_0, \theta_0) = C_{i_n}^{-1} e_i' \). Also \( A=0 \) and \( b=c \)

Then Theorem 7.6.3 and the agreement on p. 7.6.14 yield

\[ I_R = 0, \quad \psi_R = 0, \quad \psi_R = 0, \]

\[ \iota_R = \theta \frac{2}{\varepsilon \omega} \frac{e_i}{e_i'} \quad \text{--- arbitrary because of } e_i'. \]

We sum these results up in

Theorem 7.6.12. For a perfect conductor, the

\[ \text{See the proof of Theorem 1.116.} \]
The reactions are

\[ T_R = 0, \quad \eta_R = 0, \quad \psi_R = 0, \]

\[ \eta_R \text{ arbitrary.} \]

The perfect conductor is the thermal counterpart of the rigid body where \( T_R \) comes out to be arbitrary.

Since the deformation gradient has dropped out of the expressions for the reactions, perfect conductivity is automatic consistent with any kind of material symmetry that we might wish to impose. In particular, a perfect conductor might be isotropic. We did not pick this up in Theorem 7.6.7 because the constraint of perfect conductivity is not expressible by a single constraint equation of the

\[ \text{See Exercise 3.6.2.} \]
forms (TMC). Of course, in their general theory of constraints, Einstein and Nordtchev also found the notions of isotropy and perfect conductivity to be compatible.

**Isothermal**

A process for which \( \dot{\theta} = 0 \) is said to be isothermal. There does not seem to be any special name for bodies that can sustain only isothermal processes (analogous to incompressible bodies being those that can sustain only isochoric motions). Processes in which \( q = 0 \) are also occasionally called isothermal. With these cautions, we proceed.

**Definition 7.6.4.** A body \( B \) is said to be subjected to the isothermal constraint at the particle
if the material time derivative of the temperature must vanish at \( x \), i.e.,

\[
\dot{\mathbf{z}}(x, t) = 0 \quad \forall t. \quad (IC)
\]

The constraint (IC) is of the form (TRC) with \( \lambda = 0 \), \( b = 1 \), \( \zeta = 0 \), and these forms satisfy the principle of material indifference. ¹ We can then read off the following result from Theorem 7.6.3 and the agreement on p. 7.6.14.

Theorem 7.6.13. For a body subjected to the isothermal constraint, the reactions are

\[
\begin{align*}
T_R &= 0, \quad \psi_R = 0, \quad \varphi_R = 0, \\
\eta_R & \text{ arbitrary,}
\end{align*}
\]

¹ Cf., Theorem 7.6.2.
We note again that the reactions are such that the isothermal constraint is compatible with any kind of material symmetry. In particular, a fluid might be subjected to the isothermal constraint. This is consistent with our Theorem 7.6.8; however, since (TC) is not a special case (TDC), it is not consistent with Guidi and Guidugli's observation that a fluid can at most be subjected to the constraint of temperature-dependent compressibility.

Inextensibility

We saw in §2.3 that the stretch of a line

\[ \text{stretch} = \frac{\text{length after}}{\text{length before}} \]

This purely mechanical constraint could have been discussed in §3.6.

\[ \text{Roughly speaking, stretch} = \frac{\text{length after}}{\text{length before}} \]
in the direction $e_2$ ($|e_2| = 1$) in the reference configuration $x$ is $\mathbf{F}_2 e_2$. In particular, if there is no extension in the direction $e_2$, then $e_2 \cdot C_{\infty} e_2 = 1$.

Formally, we have

**Definition 7.6.5.** A body $B$ is said to be subjected to the constraint of inextensibility in the direction $e_2$ ($|e_2| = 1$) in the reference configuration at the particle $X$ iff

$$e_2 \cdot C_{\infty}(X, t) e_2 = 1 \quad \forall \ t, \quad (I),$$

To cast $(I)$ into the form $(TMC)$, we differentiate w.r.t. $t$:

$$\mathbf{g} \cdot \frac{\partial C_{\infty}(X, t)}{\partial t} e_2 = 0;$$

but by Exercise 3.6.1,
\[ \frac{\partial c_i}{\partial t} = 2 F^T D F. \]

Thus,
\[ e \cdot F^T D F e = 0. \]

We leave it as Exercise 7.6.5 to show that
\[ e \cdot F^T D F e = \left([F e] \otimes [F e]\right) \cdot D. \]

Hence, we have

\[ \text{Theorem 7.6.14. } (I) \Rightarrow \]
\[ \left([F e] \otimes [F e]\right) \cdot D = 0 \quad \forall \ t, \quad (I_2) \]

Exercise 7.6.6. Consider the converse of Theorem 7.6.14.

Of course, \( (I_2) \) is in the form (FNC) with
\[ A = [F e] \otimes [F e], \quad b = 0, \quad e = 0. \] We leave it as Exercise 7.6.7 to show that
\[ [F e] \otimes [F e] = F_n (e \otimes e) F^T_n. \]
Hence, our expression for \( A \) is consistent with the reduced form of Theorem 7.6.2 if we take \( \bar{A}^x_n (\varepsilon, \theta) \)

\[ = e \otimes e, \]

By Theorem 7.6.3 and the agreement on p. 7.6.14, we have

Theorem 7.6.15, The reactions corresponding to the constraint of inextensibility in the direction \( e \)

(in the reference configuration) are

\[ T_R = \alpha (F_e)^T \alpha (F_e), \quad (\text{uniaxial tension}) \]

\[ \gamma_R = 0, \quad \eta_R = 0, \quad \psi_R = 0. \]

Since the deformation gradient plays a prominent role in \( T_R \), not all material symmetries are compatible with the constraint of inextensibility in the
direction $e$. This should be no surprise since the
constraint is obviously highly dependent on the
particular direction $e$.

Since $e$ may vary from particle to particle,
the direction of inextensibility need not correspond
to a straight line. In particular, $e$ might be
the tangent to a smooth curve.

The constraint of inextensibility provides a
relatively simple model of materials reinforced by
inextensible cords. Of course, the concept of inextensibility
is an idealization. But it may be appropriate if the
cord material is much stiffer than the matrix (e.g., rubber
reinforced with steel wire.
Perfect Conductivity in the Direction $\mathbf{e}$

Suppose $\mathbf{e} (|\mathbf{e}| = 1)$ is the tangent vector at $\mathbf{x}$ to a curve in the reference configuration $\mathbf{x}$. The vector $\mathbf{E}_n(x,t) \mathbf{e}$ is tangent at $\mathbf{y}_n(x,t)$ to the corresponding curve at time $t$. Combining this observation with the notion of perfect conductivity leads to

Definition 7.6.6. A body $B$ is said to be a perfect conductor in the direction $\mathbf{e}$ in the reference configuration $\mathbf{x}$ at the particle $\mathbf{x}_n$ if

$$[\mathbf{E}_n(x,t) \mathbf{e}] \cdot g_{n}(x,t) = 0 \quad \forall t. \quad (PCE_e)$$

Exercise 7.6.8. Show that $(PCE_e)$, is equivalent to

$$\mathbf{e} \cdot \nabla \mathbf{E}(x,t) = 0 \quad \forall t. \quad (PCE_e)$$
Clearly \((PCE)\) is in the form of \((TMC)\) with \(A = 0, \ b = 0, \ \epsilon = E_0 \epsilon\). We note also that this is consistent with the reduced forms of Theorem 7.6.2, Theorem 7.6.3 and the agreement on p. 76.14 yield Theorem 7.6.16. For a perfect conductor in the direction \(e_3\) (in the reference configuration), the reactions are

\[ i_R = 0, \quad j_R = 0, \quad q_R = 0 \]

\[ f_R = \alpha F_0 \epsilon e_3 \]

At the end of the previous subsection, we mentioned rubber reinforced with steel wire as an example of an inextensible material. Since steel is a much better conductor of heat than rubber, it is reasonable to model
rubber reinforced with steel wire in the direction ε₀ as
a perfect conductor in the direction ε₁ as well as being
inextensible in the direction ε₂. Then the combined
reactions are

\[ T = \alpha (F_ε) \delta (F_ε) \]

\[ q = \beta F_{ε2} \]

\[ \gamma = \psi \]

\[ \gamma = 0. \]
